

# Path Coupling

## Seminar in Random Walks

Omer Paneth

November 16, 2009

- Uniform sampling using the Gibbs sampler
- Fast convergence using a coupling argument
- No general coupling for Gibbs sampler
- for q-coloring we could show fast convergence when  $q \geq 2\Delta^2$

- $M$  - Markov chain on a set  $\Omega$
- $D(\Omega, R)$  - Weighted connected undirected graph
- $\delta(x, y)$  - Weight of the shortest path  $x \rightsquigarrow y$  in  $D$

Define a stochastic process  $C$  on  $(X_t, Y_t) \in R \subset \Omega \times \Omega$  s.t.:

- Marginal distributions of  $X_t, Y_t$  are copies of  $M$
- $\exists \beta < 1, \forall (x, y) \in R,$

$$\mathbb{E}[\delta(X_1, Y_1) | (X_0, Y_0) = (x, y)] \leq \beta \cdot \delta(x, y)$$

Extend  $C$  to a coupling on  $\Omega \times \Omega$ :

For  $(x, y) \in \Omega \times \Omega$ , let  $x = x_1, x_2, \dots, x_k = y$  be the shortest path  $x \rightsquigarrow y$  in  $D$ , i.e.,  $\forall i (x_i, x_{i+1}) \in R$

- First pick  $x'_1$  according to  $M$  given  $x_1$
- For  $i$  in  $1..k - 1$ :
  - Pick  $x'_{i+1}$  according to the marginal distribution  $C(x_i, x_{i+1})$  given  $x'_i$
- Move to state  $(x'_1, x'_k) = (x', y')$

For a graph  $G(V, E)$  of maximal degree  $\Delta$  and a set  $C$  of  $q$  colors, define a chain on  $C^V$ :

- Pick at random  $v \leftarrow V, c \leftarrow C$
- If  $v$  can be colored in  $c$  color it  
Else do nothing

This is not exactly a Gibbs sampler but it still converge to the uniform distribution

# Random q-coloring - Coupling

- We will use Hamming distance -  $H(X, Y)$
- Consider the graph  $D(\Omega, R)$ , where  $\Omega = C^V$ ,  
 $R = \{(X, Y) \in \Omega \times \Omega \mid H(X, Y) = 1\}$

Coupling for  $(X, Y) \in R$ :

- Pick at random  $v \leftarrow V, c \leftarrow C$
- Try to move according to  $v, c$  in both  $X$  and  $Y$

Assuming  $X, Y$  differ only in the color of  $v_0$

- If  $v$  is  $v_0$  then  $H(X, Y)$  can decrease to 0  
 $\Pr[v = v_0 \text{ and } c \text{ is a legal color}] \geq \frac{1}{n} \left(1 - \frac{\Delta}{q}\right)$
- If  $v$  is adjacent to  $v_0$  then  $H(X, Y)$  can increase to 2  
 $\Pr[(v, v_0) \in E \text{ and } c \in \{X(v), Y(v)\}] \leq \frac{\Delta}{n} \frac{2}{q}$
- Else,  $H(X, Y)$  stays 1, so:

$$\mathbb{E}[\delta(X', Y')] < 1 - \frac{1}{n} \left(1 - \frac{\Delta}{q}\right) + \frac{\Delta}{n} \frac{2}{q} = 1 - \frac{q - 3\Delta}{n \cdot q}$$

Linear Extensions -  
Coupling

Linear Extensions -  
Analysis

- For  $q \geq 3\Delta + 1$  we can set  $\beta$  to  $1 - \frac{1}{n \cdot q}$
- $D$  has diameter  $n$
- By path coupling  $\mathbb{E}[H(X_t, Y_t)] \leq \beta^t \cdot n$
- $\Pr[X_t \neq Y_t] \leq \mathbb{E}[H(X_t, Y_t)] \leq \beta^t \cdot n$
- By coupling lemma:

$$\tau(\epsilon) \leq \left\lceil \frac{\ln(n \cdot \epsilon^{-1})}{\ln \beta^{-1}} \right\rceil = \left\lceil \frac{\ln(n \cdot \epsilon^{-1})}{\ln \left(1 + \frac{1}{n \cdot q - 1}\right)} \right\rceil$$

$$\tau(\epsilon) = O(n^2 \log(n \cdot \epsilon^{-1}))$$

# Random q-coloring - Coupling 2

We can improve the bound on  $q$  by defining a better coupling:

- Pick at random  $v \leftarrow V, c \leftarrow C$
- If  $(v, v_0) \in E$  and  $c \in \{X(v_0), Y(v_0)\}$ 
  - In  $X$ , try coloring  $v$  with rand color in  $\{X(v_0), Y(v_0)\}$
  - In  $Y$ , try coloring  $v$  with the other color
- Else, color  $X(v), Y(v)$  with  $c$

Notice that the process is still a coupling, since the probability to color  $v$  with color  $X(v_0)$  has not changed (same for  $Y(v_0)$ )

- $\Pr[(v, v_0) \in E \text{ and } X'(v) \neq Y'(v)] \leq \frac{1}{2} \frac{\Delta}{n} \frac{2}{q}$

- Similar to the previous case we get:

$$\begin{aligned}\mathbb{E}[\delta(X', Y')] &< 1 - \frac{1}{n} \left(1 - \frac{\Delta}{q}\right) + \frac{1}{2} \frac{\Delta}{n} \frac{2}{q} \\ &= 1 - \frac{q - 2\Delta}{n \cdot q}\end{aligned}$$

And the same result holds for  $q \geq 2\Delta + 1$

For states  $X, Y$  where  $H(X, Y) = 1$  define the following coupling:

- Pick at random  $v \leftarrow V$
- Find  $\nu_{X,v}$  - the distributions of possible colors for  $v$  in  $X$
- Similarly find  $\nu_{Y,v}$
- Color  $v$  in  $X$  and  $Y$  according to the optimal coupling between  $\nu_{X,v}$  and  $\nu_{Y,v}$

It is left to find out if we can find  $\beta < 1$  as required

- Linear Extensions - Analysis

Let  $P$  be a partial order on  $[n]$ . A linear extension of  $P$  is a total order (permutation) which is consistent with  $P$ .

**The problem:** Given a partial order  $P$  pick a random linear extension of  $P$ .

To sample uniformly from all linear extensions of  $P$  we will use the following chain on any linear extension  $X$  of  $P$ :

- Pick at random  $c \leftarrow \{0, 1\}$
- Pick  $p$  according to some distribution  $f$  on  $[n - 1]$
- If  $c = 1$  and transposing  $X(p)$  and  $X(p + 1)$  is consistent with  $P$ , transpose them  
Else, do nothing

- Linear Extensions - Notation
- Linear Extensions - Coupling
- Linear Extensions - Analysis

The chain defined is interesting because:

- It is irreducible, since we can get from every legal permutation  $X$  to  $Y$  by "moving" every element of  $X$  to it's new place, according to the order of  $Y$
- It is aperiodic, since it contains self loops
- The transition matrix is symmetric so the uniform distribution is reversible and stationary

It remains to show that the chain is rapidly mixing

# Linear Extensions - Notation

Denote:

- $\Omega$  is the set of all linear extensions of  $P$
- $\sigma(i, j)$  for  $0 < i < j \leq n$  is the transposition operation
- For  $\sigma(i, j)$ ,  $j - i$  is the transposition width
- $D(\Omega, R)$ , where  $R = \{(X, Y) \mid \exists i < j, \sigma(i, j)X = Y\}$
- The weight of an edge in  $R$  is its transposition width
- $\delta(X, Y)$  is the weight of the shortest path  $X \rightsquigarrow Y$  in  $D$

# Linear Extensions - Coupling

For all  $X, Y \in R$  s.t.  $\sigma(i, j)X = Y$  define the following coupling:

- Pick random  $c_0 \in \{0, 1\}$
- Pick  $p$  according to  $f$
- If  $p = i$  and  $p + 1 = j$  then  $c_1 = 1 - c_0$  else  $c_1 = c_0$
- If  $c_0 = 1$  try to apply  $\sigma(p, p + 1)$  on  $X$
- If  $c_1 = 1$  try to apply  $\sigma(p, p + 1)$  on  $Y$

For  $j - i > 1$  we have:

$$\mathbb{E}[\delta(X', Y')] \leq \delta(X, Y) + \frac{1}{2} (f(i-1) - f(i)) - f(j-1) + f(j))$$

For  $j - i = 1$  we have:

- If  $p = i - 1$  or  $p = j$ ,  $\delta(X, Y)$  will increase by 1 with probability at most  $1/2$
- If  $p = i = j - 1$ ,  $\delta(X, Y)$  will decrease by 1
- Else  $\delta(X, Y)$  will not change

# Linear Extensions - Analysis

So we get:

$$\begin{aligned}\mathbb{E}[\delta(X', Y')] &\leq \delta(X, Y) + \frac{1}{2} (f(i-1) + f(j)) - f(i) \\ &= \delta(X, Y) + \frac{1}{2} (f(i-1) - f(i)) - f(j-1) + f(j))\end{aligned}$$

# Linear Extensions - Analysis

If we pick a concave distribution  $f(i) = i(n - i)/K$  (where  $K = O(n^3)$  is a normalization factor) we get:

$$\forall i < n, f(i) - f(i - 1) = \frac{n + 1 - 2i}{K}$$

and since  $\delta(X, Y) = j - i$ :

$$\begin{aligned}\mathbb{E}[\delta(X', Y')] &\leq \delta(X, Y) + \frac{1}{2} (f(i - 1) - f(i) - f(j - 1) + f(j)) \\ &= \delta(X, Y) + \frac{1}{2K} ((n + 1 - 2j) - (n + 1 - 2i)) \\ &= \delta(X, Y) + \frac{1}{K} (i - j) \\ &= (j - i) - \frac{1}{K} (j - i) \\ &= \left(1 - \frac{1}{K}\right) \cdot \delta(X, Y)\end{aligned}$$
