## MODELS OF REPRESENTATIONS OF COMPACT

## LIE GROUPS

I. N. Bernshtein, I. M. Gel'fand, and S. I. Gel'fand

1. Let $U$ be a compact Lie group. A representation $\sigma$ of the group $U$ will be called a model if every irreducible representation $\pi$ of the group $U$ enters into $\sigma$ exactly one time. The theory of highest weight provides one method to construct such models. Namely, $\sigma$ can be realized in the space of analytic functions on the fundamental affine space of the group $U$, i.e., on the factor space $G / N$ of the complex cover $G$ of the group $U$ by the maximal unipotent subgroup $N \subset G$. The defect of this construction is that we must require that our functions be analytic. On the other hand, for the simplest group $\operatorname{SO}(3)$ there is another classical realization of a model in the space of all square-integrable functions on the two-dimensional sphere. In this note we introduce an analogous construction of a model for an arbitrary compact Lie group. Our model will be realized in a space of vector functions on the compact symmetric space of maximum rank corresponding to the group U .
2. Let $U$ be a connected compact Lie group, let $T$ be the maximal torus in $U$, and let $\Lambda$ be the lattice of characters of $T$. We shall fix a Cartan involution, i.e., an anti-automorphism $\theta: U \rightarrow U$ such that $\theta^{2}=1$ and $\theta(t)=t$ for all $t \in T$. Let us set $K=\left\{u \in U \mid \theta(u)=u^{-1}\right\}$. We shall call $K$ the involutive subgroup in $U$; this subgroup is determined by the group $U$ uniquely up to an inner automorphism of $U$. An important role will be played by the group $S=T \cap K$. It is easy to check that $S$ consists of all elements of order two in $T$, so that S is a finite commutative group of order $2^{\mathrm{r}}$, where r is the rank of U .

Example. If $\mathrm{U}=\mathrm{U}(\mathrm{n})$ and $\theta$ is a transposition, then $\mathrm{K}=O(\mathrm{n})$ and S is the group of diagonal matrices with the numbers $\pm 1$ on the main diagonal.
3. Let $\tau$ be a finite-dimensional representation of the group $K$. Our goal is to study how the representation $\operatorname{Ind}_{\mathrm{K}}^{\mathrm{U}}(\tau)$ of the group U , induced by the representation $\tau$ of the subgroup K , breaks up into irreducible components. Let $C \subset \Lambda$ be the set of all highest weight irreducible representations of $U$ (with respect to some ordering).

PROPOSITION 1. Let $\pi$ be an irreducible representation of $U$ with highest weight $\lambda$ : $T \rightarrow C^{*}$. Then $\dagger$

$$
\begin{equation*}
\left(\operatorname{Ind}_{K}^{U}(\tau), \pi\right)_{U} \leqslant\left(\left.\tau\right|_{\mathrm{S}},\left.\lambda\right|_{\mathrm{S}}\right)_{S} . \tag{*}
\end{equation*}
$$

COROLLARY. If $\left.\tau\right|_{\mathrm{S}}$ has spectrum of multiplicity one (i.e., decomposes into a direct sum of pairwise inequivalent irreducible representations), then $\operatorname{Ind}_{\mathrm{K}}^{\mathrm{U}}(\tau)$ also has spectrum of multiplicity one.
4. In what follows we shall study the conditions under which equality holds in formula (*).

PROPOSITION 2. a) For every representation $\tau$ of the group $K$ we can find $\mu \in C$ such that for every irreducible representation $\pi$ of the group $U$ with highest weight $\lambda \in \mu+C$, equality holds in formula (*).
b) If $\tau=1$ is the identity representation of K , then equality holds in formula (*). In other words, an irreducible representation $\pi$ of the group $U$ enters into $\operatorname{Ind}{ }_{K}^{U}(1)$ if and only if its highest weight $\lambda$ is even, i.e., $\lambda \in 2 \Lambda$.
$\dagger\left(\rho_{1}, \rho_{2}\right)_{\mathrm{G}}$ denotes the number of times the irreducible representation $\rho_{2}$ of the group $G$ occurs in the representation $\rho_{1}$.

[^0]5. We shall describe those representations $\tau$ for which equality always holds in formula (*).

Let $G$ be the complexification of $U$, let $H \subset G$ be the complexification of $T$, and let $\alpha$ be a root of $G$ with respect to H . We choose a homomorphism $\varphi_{\alpha}: \operatorname{SL}(2, \mathrm{C}) \rightarrow \mathrm{G}$ so that the image under $\varphi_{\alpha}$ lies in the standard three-dimensional subgroup of G corresponding to the root $\alpha$, and moreover, $\varphi_{\alpha}$ (diag $\left.\left(a, a^{-1}\right)\right) \subset$ $H$ and $\varphi_{\alpha}(\mathrm{SO}(2)) \subset \mathrm{K}$. Let $\psi_{\alpha}: \mathrm{SO}(2) \rightarrow \mathrm{K}$ be the restriction of $\varphi_{\alpha}$.

We note that the group $\mathrm{SO}(2)$ is isomorphic to the circle, and so its irreducible representations are one-dimensional and are defined by a single integer, the degree of the representation.

Definition. A representation $\tau$ of the group K will be called fine if, for every root $\alpha$, the representation $\tau \cdot \psi \alpha$ of the group $\operatorname{SO}(2)$ decomposes into a direct sum of one-dimensional representations of degrees 0,1 , and -1 .

We observe that it suffices to check this condition on one root from each orbit of the Weyl group.
THEOREM 1. If $\tau$ is a fine representation of the group $K$, then, for every irreducible representation $\pi$ of the group U, equality holds in formula (*). This property holds only for fine representations.

THEOREM 2. For every connected compact Lie group $U$ there exists a fine representation $\tau$ of the subgroup $K \subset U$ such that $\tau \mid S$ is a regular representation of $S$.

If $\tau$ is the representation mentioned in Theorem 2, then it follows from Theorem 1 that the representation $\operatorname{Ind} \mathrm{K}_{\mathrm{K}}^{U}(\tau)$ is a model for the group U . This representation is realized in the space of sections of a vector bundle over a compact symmetric space $\mathrm{U} / \mathrm{K}$ of maximal rank. The fiber of this bundle has dimen$\operatorname{sion} 2^{2}$.

We note that, in general, the representation $\tau$ in Theorem 2 is not uniquely determined. It can be shown, however, that if the factor-group $Z / Z^{0}$ of the center $Z$ of the group $U$ by the connected component of the identity $Z^{0}$ does not contain elements of order two (for example, if the center $Z$ is connected), then the representation $\tau$ in Theorem 2 is uniquely defined.
6. In this section we shall indicate for every classical compact Lie group $U$ a fine representation $\tau$ of the subgroup $\mathrm{K} \subset \mathrm{U}$ for which $\operatorname{In} \mathrm{d}_{\mathrm{K}}^{\mathrm{U}}(\tau)$ is a model. We shall denote by $\rho_{\mathrm{n}}$ the natural representation of the group $\mathrm{U}(\mathrm{n})$ in the space $\wedge^{*}\left(\mathrm{C}^{n}\right)=\underset{i=0}{n} \wedge^{i}\left(\mathrm{C}^{n}\right)$.
a) $\mathrm{U}=\mathrm{U}(\mathrm{n}), \mathrm{K}=O(\mathrm{n}) ; \tau=\rho_{\mathrm{n}} \mid \mathrm{K}$ is the natural representation of K in the space $\wedge^{*}(\mathrm{Cn})$.
a') $U=\operatorname{SU}(\mathrm{n}), \mathrm{K}=\mathrm{SO}(\mathrm{n})$; the representation $\tau$ of the group K is the restriction of the representation $\rho_{\mathrm{n}}$ on some $2^{\mathrm{n}-1}$-dimensional subspace $\mathrm{L} \subset \wedge^{*}\left(\mathrm{C}^{\mathrm{n}}\right)$. To construct the space L we consider the operator B: $\wedge^{*}(\mathrm{Cn}) \rightarrow \wedge^{*}\left(\mathrm{C}^{\mathrm{n}}\right)$ such that $\mathrm{B}^{2}=1$ and for every $o \in O(\mathrm{n})$ we have $B \cdot \rho_{n}(o)=\operatorname{det} o \cdot \rho_{n}(o) \cdot B$, and we set $L=$ $\left\{x \in \wedge^{*}\left(\mathrm{C}^{n}\right) \mid B x=x\right\}$ (the operator B is easily constructed from the ordinary operator* (see [3], p. 33)). For odd n we can take $L=\underset{i<n / 2}{\oplus} \wedge^{i}\left(\mathbb{C}^{n}\right)$.
b) $\mathrm{U}=\mathrm{S} O(2 \mathrm{n}+\varepsilon)$, where $\varepsilon=0,1, K=(O(n) \times O(n+\varepsilon)) \cap S O(2 n+\varepsilon)$; the representation $\tau$ in the space $\wedge^{*}\left(\mathrm{C}^{\mathrm{n}}\right)$ is defined by the formula $\tau\left(o \times o^{\prime}\right)=\rho_{\mathrm{n}}(o), o \in O(n), o^{\prime} \in O(n+\mathrm{E})$.
c) $\mathrm{U}=\mathrm{U}(\mathrm{n}, \mathrm{H})$ (the unitary quaternion group), $\mathrm{K}=\mathrm{U}(\mathrm{n}) ; \tau=\rho_{\mathrm{n}}$ is the natural representation of K in the space $\wedge^{*}(\mathrm{Cn})$.
7. Detailed proofs of the results stated above, and in particular, a complete construction of the models for the spinor groups and the basic groups of type $G_{2}, F_{4}, E_{6}, E_{8}$ are contained in [1].

Obviously, the construction of the models can be generalized to arbitrary semisimple Lie groups. A different construction of models, connected with the choice of other subgroups, is examined in [2] for the case of the finite Chevalley groups.

Added in Proof. D. P. Zhelobenko has brought to our attention that similar results have been obtained by Yu. B. Dzyadyk; part of these have been published in Dokl. Akad. Nauk SSSR, 220, No. 5, 10191020; No. 6, 1259-1262 (1975).
