Counting Hamilton decompositions of oriented graphs

Asaf Ferber∗ Eoin Long† Benny Sudakov‡

Abstract

A Hamilton cycle in a directed graph \( G \) is a cycle that passes through every vertex of \( G \). A Hamiltonian decomposition of \( G \) is a partition of its edge set into disjoint Hamilton cycles. In the late 60s Kelly conjectured that every regular tournament has a Hamilton decomposition. This conjecture was recently settled by Kühn and Osthus [15], who proved more generally that every \( r \)-regular \( n \)-vertex oriented graph \( G \) (without antiparallel edges) with \( r = cn \) for some fixed \( c > 3/8 \) has a Hamiltonian decomposition, provided \( n = n(c) \) is sufficiently large. In this paper we address the natural question of estimating the number of such decompositions of \( G \) and show that this number is \( n^{(1-o(1))cn^2} \). In addition, we also obtain a new and much simpler proof for the approximate version of Kelly’s conjecture.

1 Introduction

A Hamilton cycle in a graph or a directed graph \( G \) is a cycle passing through every vertex of \( G \) exactly once, and a graph is Hamiltonian if it contains a Hamilton cycle. Hamiltonicity is one of the most central notions in graph theory, and has been intensively studied by numerous researchers in recent decades. The decision problem of whether a given graph contains a Hamilton cycle is known to be \( \mathcal{NP} \)-hard and in fact, already appears on Karp’s original list of 21 \( \mathcal{NP} \)-hard problems [10]. Therefore, it is important to find general sufficient conditions for Hamiltonicity (for a detailed discussion of this topic we refer the interested reader to two surveys of Kühn and Osthus [14, 13]).

In this paper we discuss Hamiltonicity problems for directed graphs. A tournament \( T_n \) on \( n \) vertices is an orientation of an \( n \)-vertex complete graph \( K_n \). The tournament is regular if all in/outdegrees are the same and equal \((n-1)/2\). It is an easy exercise to show that every tournament contains a Hamilton path (that is, a directed path passing through all the vertices). Moreover, one can further show that a regular tournament contains a Hamilton cycle.

A tournament is a special case of a more general family of directed graphs, so called oriented graphs. An oriented graph is a directed graph obtained by orienting the edges of a simple graph (that is, a graph without loops or multiple edges). Given an oriented graph \( G \), let \( \delta^+(G) \) be its minimum outdegree, \( \delta^-(G) \) be its minimum indegree and let the semi-degree \( \delta^0(G) \) be the minimum of \( \delta^+(G) \) and \( \delta^-(G) \). A natural question, originally raised by Thomassen in the late 70s, asks to determine the minimum semi-degree which ensures Hamiltonicity in the oriented setting. Following a long line of research, Keevash, Kühn and Osthus [11] settled this problem, showing that \( \delta^0(G) \geq \left\lceil \frac{2n-1}{8} \right\rceil \) is enough to obtain a Hamilton cycle in any \( n \)-vertex oriented graph. A construction showing that this is tight was obtained much earlier by Häggkvist [9].

Once Hamiltonicity of $G$ has been established, it is natural to further ask whether $G$ contains many edge-disjoint Hamilton cycles or even a \textit{Hamilton decomposition}. A Hamilton decomposition is a collection of edge-disjoint Hamilton cycles covering all the edges of a graph. In the late 60s, Kelly conjectured (see [14, 13] and their references) that every regular tournament has Hamilton decomposition. Kelly’s Conjecture has been studied extensively in recent decades, and quite recently was settled for large tournaments in a remarkable tour de force by Kühn and Osthus [15]. In fact, Kühn and Osthus [15] proved the following stronger statement for dense $r$-regular oriented graphs (that is, oriented graphs with all in/outdegrees equal to $r$).

**Theorem 1.** Let $\epsilon > 0$ and let $n$ be a sufficiently large integer. Then, every $r$-regular oriented graph $G$ on $n$ vertices with $r \geq 3n/8 + \epsilon n$ has a Hamilton decomposition.

The bound on $r$ in this theorem is best possible up to the additive term of $\epsilon n$. Indeed, as we already mentioned above, if $r$ is smaller than $3n/8$ then $G$ may not even be Hamiltonian.

Counting various combinatorial objects has a long history in Discrete Mathematics and such problems have been extensively studied. Motivated by Theorem 1, in this paper we consider the number of distinct Hamilton decompositions of dense regular oriented graphs. One can obtain an upper bound for this question by using the famous Minc conjecture, established by Bréguen [3], which provides an upper-bound on the permanent of a matrix $A$. Let $S_n$ be the set of all permutations of the set $[n]$. The permanent of an $n \times n$ matrix $A$ is defined as $\text{per}(A) = \sum_{\sigma \in S_n} \prod_{i=1}^{n} A_{\sigma(i)}$. Note that every permutation $\sigma \in S_n$ has a cycle representation which is unique up to the order of cycles. When $A$ is a 0–1 adjacency matrix of an oriented graph (that is $A_{ij} = 1$ iff $\vec{ij} \in E(G)$), every non-zero summand in the permanent is 1 and it corresponds to a collection of disjoint cycles covering all the vertices. Hence, the permanent counts the number of such cycle factors and, in particular, gives an upper bound on the number of Hamilton cycles in the corresponding graph. For an $r$-regular oriented graph $G$ with adjacency matrix $A$, Bréguen’s Theorem asserts that

$$\text{per}(A) \leq (r!)^{n/r} = (1 - o(1))^n (r/e)^n.$$

Therefore, $G$ has at most $(1 - o(1))^n (r/e)^n$ Hamilton cycles. Note that upon removing the edges of such a cycle from $G$, we are left with an $(r - 1)$-regular oriented graph $G'$. Again by Bréguen’s Theorem, $G'$ contains at most $(1 - o(1))^n ((r - 1)/e)^n$ distinct Hamilton cycles. Repeating this process and taking the product of all these estimates, we deduce that $G$ has at most

$$\left((1 + o(1))\frac{r}{e^2}\right)^{rn}$$

Hamilton decompositions. When $r$ is linear in $n$ this behaves asymptotically as $n^{(1-o(1))rn}$.

Our first result gives a corresponding lower bound, which together with the above estimates determine asymptotically the number of Hamiltonian decompositions of dense regular oriented graphs. It is worth drawing attention to the fact that our result shows that all such graphs have roughly the same number of Hamiltonian decompositions.

**Theorem 2.** Let $c > 3/8$ be a fixed constant, let $\epsilon > 0$ be an arbitrary small constant, and let $n$ be a sufficiently large integer. Then, every $cn$-regular oriented graph $G$ on $n$ vertices contains at least $n^{(1 - \epsilon)cn^2}$ distinct Hamilton decompositions.
The main step in the proof of this theorem is to construct many almost Hamilton decompositions, each of which can be further completed to a full decomposition. This is done by extending some ideas from [6] and differs from the approach used in [15]. In particular, we obtain a new and much simpler proof for the approximate version of Kelly’s conjecture, originally established by Kühn, Osthus and Treglown in [16]. Furthermore, note that a Hamilton decomposition of a regular tournament also gives a Hamilton decomposition of the underlying complete (undirected) graph. Therefore Theorem 2 implies that, for odd \( n \), the \( n \)-vertex complete graph has \( n^{(1-o(1))n^2/2} \) Hamilton decompositions. This estimate, together with more general results concerning counting Hamilton decompositions of various dense regular graphs, was recently obtained in [8].

Another natural problem studied in this paper concerns how many edge-disjoint Hamilton cycles one can find in a given (not necessarily regular) oriented graph. Observe that if an oriented graph \( G \) contains \( r \) edge-disjoint Hamilton cycles, then their union gives a spanning, \( r \)-regular subgraph of \( G \). We refer to such a subgraph as an \( r \)-factor of \( G \). Given an oriented graph \( G \), let \( \text{reg}(G) \) be the maximal integer \( r \) for which \( G \) contains an \( r \)-factor. Clearly, \( G \) contain at most \( \text{reg}(G) \) edge-disjoint Hamilton cycles. We propose the following conjecture which, if true, is best possible.

**Conjecture 3.** Let \( c > 3/8 \) be a fixed constant and let \( n \) be sufficiently large. Let \( G \) be an oriented graph on \( n \) vertices with \( \delta^0(G) \geq cn \). Then, \( G \) contains \( \text{reg}(G) \) edge-disjoint Hamilton cycles.

Our second result gives supporting evidence for this conjecture, proving that such oriented graphs \( G \) contain \((1-o(1)) \text{reg}(G)\) edge-disjoint Hamilton cycles.

**Theorem 4.** Let \( c > 3/8 \) and \( \varepsilon > 0 \) be fixed constants and let \( n \) be sufficiently large. Let \( G \) be an oriented graph on \( n \) vertices with \( \delta^0(G) \geq cn \). Then, \( G \) contains a collection of \((1-\varepsilon) \text{reg}(G)\) edge-disjoint Hamilton cycles.

This theorem follows immediately from our proof of Theorem 2. For a regular tournament Theorem 4 implies an approximate version of Kelly’s Conjecture from [16].

**Notation:** Given an oriented graph \( G \) and a vertex \( v \in V(G) \), we let \( d_G^+(v) \) and \( d_G^-(v) \) to denote the out- and in-degree of \( v \), respectively. We omit the subscript \( G \) whenever there is no chance of confusion. We also define \( \delta^+(G) := \min_v d^+(v) \), \( \delta^- := \min_v d^-(v) \), \( \Delta^+(G) := \max_v d^+(v) \), \( \Delta^-(G) := \max_v d^-(v) \), and set \( \delta^0(G) = \min\{\delta^+(G), \delta^-(G)\} \) and \( \Delta^0(G) = \max\{\Delta^+(G), \Delta^-(G)\} \). We also write \( a \pm b \) to denote a value which lies in the interval \([a-b, a+b]\).

## 2 Tools

In this section we have collected a number of tools to be used in the proofs of our results.

### 2.1 Chernoff’s inequality

Throughout the paper we will make extensive use of the following well-known bound on the upper and lower tails of the Binomial distribution, due to Chernoff (see Appendix A in [1]).

**Lemma 5 (Chernoff’s inequality).** Let \( X \sim \text{Bin}(n, p) \) and let \( \mathbb{E}(X) = \mu \). Then

- \( \mathbb{P}[X < (1-a)\mu] < e^{-a^2\mu/2} \) for every \( a > 0 \);
\[ \mathbb{P}[X > (1 + a)\mu] < e^{-a^2\mu/3} \text{ for every } 0 < a < 3/2. \]

Remark 6. These bounds also hold when \( X \) is hypergeometrically distributed with mean \( \mu \).

### 2.2 Perfect matchings in a bipartite graph

Here we present a number of results related to perfect matchings in bipartite graphs. The first result is a criterion for the existence of \( r \)-factors in bipartite graphs, due to Gale and Ryser (see [7], [17]).

**Theorem 7.** Let \( G = (A \cup B, E) \) be a bipartite graph with \(|A| = |B| = m\), and let \( r \) be an integer. Then \( G \) contains an \( r \)-factor if and only if for all \( X \subseteq A \) and \( Y \subseteq B \)

\[ e_G(X, Y) \geq r(|X| + |Y| - m). \]

Next we present Brégman’s Theorem which provides an upper bound for the number of perfect matchings in a bipartite graph based on its degrees (see e.g. [1] page 24).

**Theorem 8.** (Brégman’s Theorem) Let \( G = (A \cup B, E) \) be a bipartite graph with \(|A| = |B| = m\). Then the number of perfect matchings in \( G \) is at most

\[ \prod_{a \in A} (d_G(a)!)^{1/d_G(a)}. \]

**Remark 9.** It will be useful for us to give an upper bound with respect to the maximum degree of \( G \). Suppose that \(|A| = |B| = m\) and let \( \Delta := \Delta(G) \). Using Theorem 8 and Stirling’s approximation, one obtains that the number of perfect matchings in \( G \) is at most

\[ (\Delta!)^{m/\Delta} \leq (8\Delta)^{m/\Delta} \left( \frac{\Delta}{e} \right)^m. \]

Lastly, we require the following result which provides a lower bound for the number of perfect matchings in a regular bipartite graph. This result is known as the Van Der Waerden Conjecture, and it was proven by Egorychev [4], and independently by Falikman [5].

**Theorem 10.** (Van Der Waerden’s Conjecture) Let \( G = (A \cup B, E) \) be a \( d \)-regular bipartite graph with both parts of size \( m \). Then the number of perfect matchings in \( G \) is at least

\[ d^m \frac{m!}{m^m} \geq \left( \frac{d}{e} \right)^m. \]

### 2.3 Hamilton paths, cycles and absorbers

We make use of the following theorem of Keevash, Kühn and Osthus [11].

**Theorem 11.** Every \( n \)-vertex oriented graph \( G \) with \( \delta^0(G) \geq (3n - 4)/8 \) contains a Hamilton cycle, provided \( n \) is sufficiently large.

We also make use of the following related result of Kelly, Kühn and Osthus, which follows immediately from the proof of the main theorem in [12].
Theorem 12. Let $c > 3/8$ be a constant and $n$ be sufficiently large. Suppose that $G$ is an oriented graph on $n$ vertices with $\delta^0(G) \geq cn$, and let $x, y \in V(G)$ be any two distinct vertices. Then there is a Hamilton path in $G$ with $x$ as its starting point and $y$ as its final point.

Before describing the next tool we need the following definition.

Definition 13. Given an $n$-vertex oriented graph $G$, a subgraph $D \subseteq G$ is said to be a $\delta$-absorber if, for any given $d$-regular subgraph $T$ which is edge-disjoint from $D$ with $d \leq \delta n$, the oriented graph $D \cup T$ has a Hamilton decomposition.

The following result is the main ingredient in the seminal paper of Kühn and Osthus in which they solved Kelly’s conjecture [15]. Roughly speaking, the theorem states that there are $\delta$-absorbers for arbitrarily small $\delta$ in any sufficiently large regular oriented graph. This refined version follows immediately from the directed version of Theorem 3.16 in [14].

Theorem 14. Let $\varepsilon > 0$ and $c > 3/8$ be two constants. Then, there is $\delta > 0$ such that for sufficiently large $n$ the following holds. Suppose that $G$ is an $n$-vertex oriented graph with $\delta^0(G) \geq cn$. Then $G$ contains a $\delta$-absorber $A$ as an oriented subgraph, where $A$ is $r$-regular with $r \leq \varepsilon n$.

3 Almost Hamilton decompositions of special oriented graphs

Our aim in this section is to show how certain special oriented graphs can be almost decomposed into Hamilton cycles.

3.1 Completing one Hamilton cycle

The following simple lemma will allow us to complete disjoint directed paths into Hamilton cycles.

Lemma 15. Let $c > 3/8$ and $a, N \in \mathbb{N}$ with $a \ll \frac{N}{\log N}$ and $N$ sufficiently large. Let $F$ be an oriented graph with $|V(F)| = N$ and $\delta^0(F) \geq cN$. Let $\{P_i\}_{i \in [a]}$ be a collection of vertex disjoint oriented paths, each of which is disjoint to $F$. Let $x_i$ and $y_i$ to denote the first and last vertices of $P_i$, for each $i$, and assume that $d^-(x_i, F), d^+(y_i, F) \geq 2a$. Then there is a cycle $C$ with the following properties:

1. Each $P_i$ appears as a segment of $C$;
2. $F \subseteq V(C)$.

Proof of Lemma 15. For each $i \in [a]$ select $t_i \in N^-(x_i)$ and $s_i \in N^+(y_i)$ such that all $2a$ vertices are distinct. Note that this is possible as $d^-(x_i, F), d^+(y_i, F) \geq 2a$. Let $S = \{s_i : i \in [a]\}, T = \{t_i : i \in [a]\}$ and $W = V(F)$.

Let us create a partition of $W$ into $a$ sets, $W_1, \ldots, W_a$, by assigning $s_i$ and $t_i+1$ to $W_i$ for all $i \in [a]$ (taking $a + 1$ to be 1) and by randomly assigning each vertex $v \in W \setminus (S \cup T)$ to one of the sets uniformly and independently at random. Now, let $\varepsilon_0 = (c - 3/8)/4 > 0$ and consider the events:

\[ A = \{ |W_i| \in (1 \pm \varepsilon_0) \frac{|W|}{a} \text{ for all } i \in [a] \} \]

\[ B = \{ d^F_{|W_i|}(v) \geq (c - \varepsilon_0) \frac{|W|}{a} \text{ for all } v \in W \text{ and } i \in [a] \} \]
As \( \mathbb{E}(|W_r|) = \frac{|W|}{a} \), using that \( N \gg a \log a \) and Chernoff’s inequality, we obtain

\[
P[A^c] \leq 2m \exp \left( -\frac{\varepsilon_0^2|W|}{3a} \right) = o(1).
\]  

(1)

Also, as \( \delta^0(F) \geq cN = c|W| \) and all but at most \( 2a \) vertices were assigned randomly, we have

\[
\mathbb{E}(d^+(v, W_i)) \geq \frac{|W_i| - 2a}{a} = \frac{|W|}{a} - 2.
\]

Again using that \( |W| \gg a \log N \) together with Chernoff’s inequality, we have

\[
P[B^c] \leq 2N \exp \left( -\Theta\left(\frac{\varepsilon_0^2|W|}{a}\right) \right) = o(1).
\]  

(2)

Combining (1) with (2) we conclude \( \mathbb{P}(A \cap B) > 0 \). Fix a partition \( W_1, \ldots, W_a \) such that \( A \cap B \) holds.

To complete the proof, set \( F_i := F[W_i] \) for each \( i \in [a] \). As \( A \cap B \) holds, we have

\[
\delta^0(F_i) \geq (c - \varepsilon_0)\frac{|W_i|}{a} \geq (c - 3\varepsilon_0)|V(F_i)| = (3/8 + \varepsilon_0)|V(F_i)|.
\]

Therefore, using that \( |V(F_i)| \geq (1 - \varepsilon_0)|W_i|/a \geq N/2a \gg \log N \) and \( N \) is sufficiently large, it follows from Theorem 12 that \( F_i \) contains a Hamilton path \( I_i \) from \( s_i \) to \( t_i+1 \), for each \( i \). All in all, the cycle \( C = P_1I_1P_2I_2 \ldots P_aI_aP_1 \) (with the connecting edges \( y_is_i \) and \( t_i+1x_{i+1} \)) gives the desired cycle. This completes the proof of the lemma.

3.2 Completing ‘many’ edge-disjoint Hamilton cycles

Next we will show how to repeatedly apply Lemma 15 to obtain ‘many’ edge-disjoint Hamilton cycles. Before stating this result we introduce the following definitions.

**Definition 16.** Let \( G \) be an oriented graph.

1. A path cover of \( G \) of size \( a \) is a collection of \( a \) vertex disjoint directed paths in \( G \) which cover all vertices in \( V(G) \).

2. An \( (a, t)_P \)-family is a collection of \( t \) edge-disjoint paths covers of \( G \), each of which is of size at most \( a \).

3. Let \( \mathcal{P}(G, a, t) \) denote the set of all \( (a, t)_P \)-families in \( G \).

4. Given \( P \in \mathcal{P}(G, a, t) \), let \( G_P \) denote the oriented subgraph \( G_P = \bigcup_{P \in \mathcal{P}} E(P) \).

**Remark:** The above definitions include the possibility of paths of length 0, i.e. isolated vertices.

One can think about a path cover \( P \) of small size as an ‘almost Hamilton cycle’, in the sense that by adjoining a small number of edges to \( P \) we can obtain a Hamilton cycle. Our aim in the following lemma is to show how, given ‘many’ edge-disjoint path covers, one can build ‘many’ edge disjoint Hamilton cycles.
Lemma 17. Let \( c > 3/8 \) and let \( a, b, n, s, t \in \mathbb{N} \) with \( t + a \log n \ll s \ll n \). Suppose that \( H \) is an \( n \)-vertex oriented graph with partition \( V(H) = U \cup W \), where \( |W| = s \), with the following properties:

1. There is \( P \in \mathcal{P}(H[U], a, t) \);
2. \( \delta^0(H_P[U]) \geq t - b \);
3. \( d^\pm(u, W) > 2a + b \) for all \( u \in U \);
4. The oriented subgraph \( F = H[W] \) satisfies \( \delta^0(F) \geq c|W| \);

Then \( H \) contains a family \( \mathcal{C} = \{C_1, \ldots, C_t\} \) of \( t \) edge disjoint Hamilton cycles, where each cycle \( C_i \) contains all the paths in \( \mathcal{P}_i \) as segments.

Proof. Let \( P \in \mathcal{P}(H[U], a, t) \) and write

\[
P = \{P_j \mid j \in [t]\}.
\]

For each \( j \), let \( \mathcal{P}_j = \{P_{j,r}\}_{r \in [R_j]} \) denote the collection of all directed paths in the path cover \( \mathcal{P}_j \). As \( \mathcal{P}_j \) has size at most \( a \), we have \( R_j \leq a \).

Now we wish to turn each \( \mathcal{P}_j \) into a Hamilton cycle \( C_j \) of \( H \) in such a way that

(i) all the paths in \( \mathcal{P}_j \) are segments of \( C_j \), and

(ii) \( C_i \) and \( C_j \) are edge-disjoint for all \( i \neq j \).

This will be carried out over a sequence of steps where in step \( j \) we have already selected \( C_1, \ldots, C_{j-1} \), and the cycle \( C_j \) is chosen by showing that the oriented graph \( H_j = H \setminus \left( \bigcup_{i \leq j-1} E(C_i) \right) \) satisfies the requirements of Lemma 15. Let us fix \( c > c' > 3/8 \).

Suppose that we have already found \( C_1, \ldots, C_{j-1} \) and we wish to find \( C_j \). Let \( x_i \) and \( y_i \) denote the start and end vertices of \( P_{j,i} \), for all \( i \leq R_j \). First note that by property 3, each vertex \( u \in \{x_i, y_i \mid i \leq R_j\} \) satisfies \( d^\pm(u, W) > 2a + b \). By property 2, each vertex \( v \) appears the first vertex of at most \( b \) paths and as the last vertex of at most \( b \) paths (otherwise \( v \) would have in-degree or out-degree less than \( t - b \) in \( H_P(U) \)). Therefore, for all \( u \in U \) we have

\[
d^+_H(u, W) \geq 2a.
\]

Second, as the edges of less than \( j \) Hamilton cycles have been deleted from \( H \), from property 4, we find that \( F_j = H_j[W] \) satisfies \( \delta^0(F_j) \geq c|W| - j + 1 \geq c'|W| \), using \( |W| = s \gg t \geq j \). Lastly, we have \( |W| = s \gg a \log n \gg a \log s \) by hypothesis.

All combined, we have shown that the graph \( H_j \) satisfies the conditions of Lemma 15 with \( N = |W| \). Therefore Lemma 15 guarantees the cycle \( C_j \) exists. Thus we can find \( C_1, \ldots, C_t \), as required. \( \Box \)

4 Path covers of oriented graphs

In the previous section we have shown how to extend edge disjoint path covers to edge disjoint Hamilton cycles in certain special oriented graphs. In this section we will show how to located such path covers, using a number of well-known matching results. The main result of the section is the following:
Lemma 18. Let \( m, r \in \mathbb{N} \) with \( r \geq m^{49/50} \) and \( m \) sufficiently large. Suppose that \( H \) is an \( m \)-vertex oriented graph with
\[
r - r^{3/5} \leq \delta^0(H) \leq \Delta^0(H) \leq r + r^{3/5}.
\]
Then, taking \( a = m/\log^4 m \) and \( t = r - m^{24/25} \log m \), the following hold:

1. There is a set \( S \subseteq \mathcal{P}(H,a,t) \) with \( |S| \geq r^{(1-o(1))rm} \);
2. For all \( \mathbf{P} \in S \) the oriented subgraph \( H_{\mathbf{P}} \) satisfies \( \delta^0(H_{\mathbf{P}}) \geq r - m/\log^4 m \).

4.1 Finding \( r \)-factors in bipartite graphs

We show that given a dense bipartite graph \( G = (A \cup B, E) \) which is ‘almost regular’, \( G \) contains a spanning \( r \)-regular subgraph (an \( r \)-factor), with \( r \) very close to \( \delta(G) \).

Lemma 19. Let \( \alpha \geq 1/2 \), \( m \in \mathbb{N} \) and \( \xi = \xi(m) \geq 0 \). Suppose \( G = (A \cup B, E) \) is a bipartite graph with \( |A| = |B| = m \) and \( \alpha m + \xi \leq \delta(G) \leq \Delta(G) \leq \alpha m + \xi + \xi^2/m \). Then \( G \) contains an \( \alpha m \)-factor.

Proof. By Theorem 7, to prove the lemma it suffices to show that for all \( X \subseteq A \) and \( Y \subseteq B \) we have
\[
e_G(X,Y) \geq r(|X| + |Y| - m).
\] (3)

Given such sets \( X \) and \( Y \), let \( x = |X| \) and \( y = |Y| \). We may assume that \( x \leq y \), as the case \( y \leq x \) follows by symmetry. We will make use of the following two trivial estimates for \( e_G(X,Y) \):

(i) \( e_G(X,Y) \geq x(\delta(G) + y - m) \);
(ii) \( e_G(X,Y) = e_G(X,B) - e_G(X,B \setminus Y) \geq \delta(G)x - \Delta(G)(m - y) \).

The required bound follows from the following cases.

Case 1: \( x + y \leq m \). In this case (3) trivially holds.

Case 2: \( x \leq y \) and \( x \leq \delta(G) \). In this case, note that since \( y - m \leq 0 \) we obtain
\[
x(\delta(G) + y - m) \geq \delta(G)(x + y - m).
\]
which by (i) proves (3).

Case 3: \( x \leq y \), and \( x > \delta(G) \). Observe that in this case since \( \alpha \geq 1/2 \) we have
\[
x + y - m \geq 2\delta(G) - m \geq 2\xi.
\] (4)

Also, from (ii), we have
\[
e_G(X,Y) \geq \delta(G)x - \Delta(G)(m - y) \geq \alpha m(x + y - m) + \xi(x + y - m) - \frac{\xi^2}{m}(m - y). \] (5)

Combining (4) with (5) and using that \( x + y \geq m \), we conclude that
\[
\alpha m(x + y - m) + \xi(x + y - m) - \frac{\xi^2}{m}(m - y) \geq \alpha m(x + y - m) + 2\xi^2 - \xi^2 \geq \alpha m(x + y - m),
\]
which again proves (3). This completes the proof. \( \square \)
Using the previous lemma we obtain the following corollary, which shows that by adjoining a small number of edges to an almost regular bipartite graph, one can obtain a regular bipartite graph.

**Corollary 20.** Let \(d, m \in \mathbb{N}, d \leq m/2 \) and \(\xi = \xi(m) \geq 0\). Suppose that \(G = (A \cup B, E)\) is a bipartite graph with \(|A| = |B| = m\) and that \(d - \xi - \ell^2/m \leq \delta(G) \leq \Delta(G) \leq d - \xi\). Then there is a bipartite \(d\)-regular graph \(H = (A \cup B, E')\) which contains \(G\) as a subgraph.

**Proof.** Given \(G\) as in the lemma, consider the graph \(G^c = (A \cup B, E^c)\) where \(e \in E^c\) if and only if \(e \notin E\). Clearly \(m - d + \xi \leq \delta(G^c) \leq \Delta(G^c) \leq m - d + \xi + \xi^2/m\). Therefore, Lemma 19 guarantees a \((m - d)\)-regular subgraph \(S \subseteq G^c\). Letting \(H := S^c\) completes the proof. □

### 4.2 Small subgraphs contribute many edges to few matchings

**Lemma 21.** Let \(m, r \in \mathbb{N}\) with \(r \geq m^{24/25}\) and \(m\) sufficiently large. Suppose that \(G = (A \cup B, E)\) is a bipartite graph with \(|A| = |B| = m\) and that \(E = E_1 \cup E_2\) is a partition of \(E\). For \(i \in \{1, 2\}\) let \(H_i\) be the spanning subgraph of \(G\) induced by the edges in \(E_i\). Suppose also that:

1. \(G\) is \(r\)-regular, and
2. \(d_{H_2}(v) \leq 2m^{5/6}\) for all \(v \in A \cup B\).

Then \(G\) contains at least \((1 - o(1)) \left(\frac{r}{\ell}\right)^m\) perfect matchings, each with at most \(m^{7/8}\) edges from \(E_2\).

**Proof.** Set \(s = 2m^{5/6}\) and \(\ell = m^{7/8}\). First note that since \(G\) is \(r\)-regular, by Theorem 10, the number of perfect matchings in \(G\) is at least \((\frac{r}{\ell})^m\). Therefore it is enough to show that at most \(o(1)(r/e)^m\) matchings of \(G\) contain at least \(\ell\) edges from \(E_2\).

Now given a matching \(M \subseteq E_2\) of size \(\ell\), let \(G'\) be the subgraph of \(G\) obtained by deleting the vertices covered by \(M\). Clearly \(\Delta(G') \leq r\) and \(|V(G')| = 2(m - \ell)\). By Remark 9 it follows that the number of ways to complete \(M\) into a perfect matching is at most

\[
\left(8\Delta\right)^{m-\ell} \left(\frac{r}{\ell}\right)^{m-\ell} \leq (8r)^{m^{1/25}} \left(\frac{e}{r}\right)^{\ell} \left(\frac{r}{e}\right)^m.
\]

However, the number of matchings of size \(\ell\) in \(H_2\) is at most \(m^{7/8}\) \(\ell\). Therefore the number of perfect matchings of \(G\) with at least \(\ell\) edges from \(E_2\) is at most

\[
(8r)^{m^{1/25}} \left(\frac{e^2 ms}{r\ell}\right)^{\ell} \left(\frac{r}{e}\right)^m \leq (8m)^{m^{1/25}} \left(\frac{2e^2 m^{1/25}}{m^{24}}\right)^{m^{7/8}} \left(\frac{r}{e}\right)^m = o(1) \left(\frac{r}{e}\right)^m.
\]

This completes the proof of the lemma. □

### 4.3 Decomposing almost regular bipartite graphs into large matchings

The following definition is convenient.

**Definition 22.** Let \(G = (A \cup B, E)\) be a bipartite graph.

1. Given two integers \(a\) and \(t\), we define an \((a, t)_{\mathcal{M}}\)-family in \(G\) to be a collection of \(t\) edge-disjoint matchings in \(G\), each of which of size at least \(a\).
2. Let $\mathcal{M}(G, a, t)$ denote the collection of all $(a, t)_{\mathcal{M}}$-families in $G$.

3. Given $M \in \mathcal{M}(G, a, t)$, we let $G_M$ to denote the spanning subgraph of $G$ consisting of the edge set $\bigcup_{M \in \mathcal{M}} E(M)$.

Our main aim in the following lemma is to show that if $G = (A \cup B, E)$ is an almost $r$-regular bipartite graph with $|A| = |B|$, then for many elements $M \in \mathcal{M}(G, a, t)$, where $a \approx |A|$ and $t \approx r$, the graph $G_M$ is also almost regular.

**Lemma 23.** Let $\varepsilon > 0$ and $m, r \in \mathbb{N}$ with $m$ sufficiently large and $2m^{24/25} \leq r \leq (1 - \varepsilon)m/2$. Suppose that $G = (A \cup B, E)$ is a bipartite graph with $|A| = |B| = m$ and $r \leq \delta(G) \leq \Delta(G) \leq r + r^{2/3}$. Then, taking $t = r - m^{24/25}$ and $a = m - m^{7/8}$, the following hold:

1. There is $\mathcal{M} \subset \mathcal{M}(G, a, t)$, with $|\mathcal{M}| = r^{(1 - o(1))rm}$;

2. For each $M \in \mathcal{M}$, the subgraph $G_M$ has minimum degree at least $t - 2m^{5/6}$.

**Proof.** Set $\xi = m^{5/6}$ and $r' = r + \xi + \xi^2/m$. Then, using that $r^{2/3} \leq m^{2/3} = \xi^2/m$, combined with the hypothesis of the lemma, we have

$$r' - \xi - \xi^2/m = r \leq \delta(G) \leq \Delta(G) \leq r + r^{2/3} = r' - \xi.$$ 

Thus by Corollary 20 there is an $r'$-regular graph $H = (A \cup B, E')$ which contains $G$ as a subgraph. Set $E_1 := E(G)$ and $E_2 := E(H) \setminus E_1$. By the above, we have

$$d_{E_2}(v) \leq r' - r = \xi + \frac{\xi^2}{2m} \leq 2m^{5/6} \quad (6)$$

for all $v \in A \cup B$.

We will now show, using Lemma 21, that there are many ways to build a sequence $(M_1, \ldots, M_t)$ of edge disjoint perfect matchings in $H$, where each matching contains at least $a$ edges from $E_1$. To do this, begin by setting $H_0 := H$. Having selected $M_1, \ldots, M_{i-1}$, set $H_i := H \setminus \bigcup_{j<i} E(M_j)$ and note that $H_i$ is $(r' - i + 1)$-regular. Since $r' - i \geq r - t \geq m^{24/25}$ and by (6), we can apply Lemma 21 to $H_i$ to find at least $(1 - o(1))(\frac{r' - i + 1}{r})^m$ perfect matchings of $H_i$ with at least $a$ edges in $E_1$. Multiplying all this estimates gives at least

$$\prod_{i=1}^{t} (1 - o(1)) \left( \frac{r' - i + 1}{e} \right)^m = r^{(1 - o(1))tm} = r^{(1 - o(1))rm}$$

possible choices for $(M_1, \ldots, M_t)$.

To complete the proof, simply note that each sequence $(M_1, \ldots, M_t)$ above gives rise to an $(a, t)_{\mathcal{M}}$-family of $G$, given by $M = \{M_i \cap E_1 : i \in [t]\}$. As each $M$ can occur at most $t!$ times in this way, these sequences give rise to $\mathcal{M} \subset \mathcal{M}(G, a, t)$ with

$$|\mathcal{M}| \geq \frac{1}{t!} \times r^{(1 - o(1))rm} = r^{(1 - o(1))rm}.$$ 

Lastly, for each such $(a, t)_{\mathcal{M}}$-family $M$, the minimum degree of $G_M$ is at least $t - 2m^{5/6}$ by (6). This completes the proof of the lemma. 

\ Quadratic 

4.4 Path covers in almost regular oriented graphs

We are now ready to complete the proof of Lemma 18.

Proof of Lemma 18. Let \( b = 2 \log^4 m \) and select a partition \( V(H) = V_1 \cup \ldots \cup V_b \) uniformly at random, where \( |V_i| \in \{ \lfloor m/b \rfloor, \lceil m/b \rceil \} \) holds for all \( i \in [b] \). For convenience we will assume \( |V_i| = m'/b \) for all \( i \in [b] \), although this assumption is easily removed. By Chernoff’s inequality, with probability \( 1-o(1) \) we find that for all \( v \in V(H) \) and \( j \in [b] \) we have

\[
d_{ij}^H(v, V_j) = d_{ij}^H(v) / b + 4 \sqrt{m' \log m} = d + d^{2/3}/2, \tag{7}
\]

where \( d = r/b \). Fix a choice of partition such that (7) holds.

Now consider the complete directed graph on \( b \) vertices, denoted by \( D_b \) (this graph contains both directed edges \((u, v)\) and \((v, u)\) for all pairs of distinct vertices \( u, v \)). By a result of Tillson [18], the complete digraph \( D_b \) has an edge decomposition into \( b \) directed Hamilton paths \( Q_1, \ldots, Q_b \). Each such path \( Q_i = v_{i_1} \ldots v_{i_b} \) naturally corresponds to an oriented subgraph \( H_i \) of \( H \) consisting of all edges in \( B_{ij} := \overrightarrow{H}[V_i, V_{ij+1}] \) for \( j \in [b-1] \). As the paths \( \{ Q_i \}_{i \in [b]} \) are edge disjoint, so are the oriented subgraphs \( \{ H_{ij} \}_{j \in [b]} \). Note that as \( B_{ij} \) only consists of edges oriented from \( V_{ij} \) to \( V_{ij+1} \), we can view \( B_{ij} \) as a bipartite graph by ignoring the orientation of its edges.

Our aim now is to show that each oriented graph \( H_i \) has many paths covers. Let us fix such a \( H_i \) and assume without loss of generality that \( H_i \) is given by the path \( Q_i = v_1 \ldots v_b \), so that \( B_{ij} = \overrightarrow{H}[V_{ij}, V_{ij+1}] \) for all \( j \in [b-1] \). The following observation is key:

Observation 24. Suppose that \( M_j \) is a matching of size at least \( m' - \ell \) in \( B_{ij} \) for all \( j \in [b-1] \). Then \( \cup M_j \) is a path cover of \( H_i \). Moreover, as \( \cup M_j \) has at least \( (m' - \ell)(b-1) \) edges and \( H_i \) has \( m \) vertices, such path covers are of size at most \( m' + b\ell \).

We now exploit this observation using Lemma 23. Note that \( d - d^{2/3}/2 \geq 2m^{24/25} \). Secondly, by (7) for all \( j \in [b-1] \) we have

\[
d - d^{2/3}/2 \leq \delta^0(B_{ij}) \leq \Delta^0(B_{ij}) \leq d + d^{2/3}/2.
\]

Therefore, we can apply Lemma 23 to \( B_{ij} \), taking \( a' = m' - (m')^{7/8} \) and \( t' = d - d^{2/3}/2 - (m')^{24/25} \), to get

(a) \( \mathcal{M}_{ij} \subseteq \mathcal{M}(B_{ij}, a', t') \) with \( |\mathcal{M}_{ij}| = d^{(1-o(1))dm'} \);

(b) For all \( M_{ij} \in \mathcal{M}_{ij} \), letting \( B := B_{ij} \), the graph \( B_{M_{ij}} \) has minimum degree at least \( t' - 2(m')^{5/6} \).

Let us now fix \( M_{ij} \in \mathcal{M}_{ij} \) for all \( j \in [b-1] \). As each \( M_{ij} \) consist of \( t' \) edge disjoint matchings, by Observation 24 we can use \( \{ M_{ij} \}_{j \in [b-1]} \) to construct \( t' \) edge disjoint path covers of \( H_i \), each of size at most \( m' + b(m')^{7/8} \leq n/\log^4 n = a \). Furthermore, it is easy to see that different choices of \( \{ M_{ij} \}_{j \in [b-1]} \) give rise to a different collection of path covers. Combined with (a), this gives at least

\[
\prod_{j \in [b-1]} |\mathcal{M}_{ij}| \geq d^{(1-o(1))(b-1)dm/b} = d^{(1-o(1))dm}.
\]

distinct \((a, t')_{p}\)-families of \( H_i \).
Now we have partitioned $H$ into $b$ edge-disjoint oriented graphs $H_1, \ldots, H_b$, each of which consists of at least $d(1-o(1))dmb$ distinct $(a,t')\mathcal{P}$-families. Further, distinct choice of such families from each $H_i$ yield distinct $(a,bt')\mathcal{P}$-family of $H$. Taking $t = bt' \geq r - 2b(m')^{24/25} \geq r - m^{24/25} \log m$, it follows that there is $S \subset \mathcal{P}(H,a,t)$ with

$$|S| \geq d(1-o(1))dmb = d(1-o(1))r_m = r(1-o(1))r_m.$$  

Here we have used that $b = 2\log^4 m$, that $d = r/b$ and that $r \geq d/2b$, giving $b^{-r_m} = r^{-o(r_m)}$.

To complete the proof of the lemma, it only remains to prove the following:

**Claim 25.** For each $P \in S$ we have $\delta^0(H_P) \geq r - m/\log^4 m$.

To see this, simply note that by construction

$$E(H_P) = \bigcup_{i,j} E(B_{M_{ij}})$$

for some choices of $M_{ij} \in \mathcal{M}_{ij}$ where $i \in [b]$ and $j \in [b-1]$. Given $v \in V_k$ say, the out-edges of $v$ in $H_P$ are therefore those out-edges of $v$ in $B_{M_{ij}}$, where $i_j = k$. However, $i_j = k$ only occurs when an out-edge of $v_k$ appears in $Q_i$, which happens exactly $b - 1$ times, since $Q_1, \ldots, Q_b$ forms a Hamilton path decomposition of $D_b$. Combined with (b), $t' = d - d^{2/3}/2 - (m')^{24/25}$ and $d = r/b$, we find

$$d_{H_P}^+(v) \geq (b-1)(t' - 2(m')^{5/6}) \geq bt' - t' - 2b(m')^{5/6} \geq r - t' - 4b(m')^{24/25} \geq r - 2m' = r - m/\log^4 m.$$  

As an identical argument lower bounds the $d_{H_P}^-(v)$, this completes the proof of the claim, and hence the proof of the lemma.

\[
\square
\]

## 5 Partitions of oriented graphs

In this final section before the proof of Theorem 4 and Theorem 2 we prove a technical lemma which will allow us to decompose oriented graphs as given in Theorem 4 into smaller subgraphs, each of which satisfy the hypothesis of Lemma 17 and Lemma 18.

**Lemma 26.** Let $\beta \geq \alpha > \varepsilon > 0$, let $K,d,n \in \mathbb{N}$, with $n$ sufficiently large, $d = \alpha n$ and $K = \log n$. Suppose that $G$ is an oriented graph with $\delta^0(G) \geq \beta n$ and that $D$ is a $d$-factor of $G$. Then there are $K^3$ edge-disjoint spanning subgraphs $H_1, \ldots, H_{K^3}$ of $G$ with the following properties:

1. For each $H_i$ there is a partition $V(G) = U_i \cup W_i$ with $|W_i| = n/K^2 \pm 1$;
2. Letting $D_i = H_i[U_i]$, for some $r \geq (1 - 2\varepsilon)d/K^3$ we have

$$r - r^{3/5} \leq \delta^0(D_i) \leq \Delta^0(D_i) \leq r + r^{3/5};$$
3. Letting $E_i = H_i[U_i,W_i]$ we have $d_{E_i}^+(u,W_i) \geq \varepsilon |W_i|/4K$ for all $u \in U_i$;
4. Letting $F_i = H_i[W_i]$ we have $\delta^0(F_i) \geq (\beta - \varepsilon)|W_i|$.
Proof. To begin, select \( K \) partitions of \( V(G) \) uniformly and independently at random where, for each \( k \in [K] \), we partition \( V(G) \) into \( K^2 \) sets, \( V(G) = \bigcup_{\ell \in[K^2]} S_{k,\ell} \) with \( |S_{k,\ell}| \in \{ \lfloor n/K^2 \rfloor, \lceil n/K^2 \rceil \} \). Note that for each \( k \in [K] \) and \( v \in V(G) \) there exists a unique \( \ell := \ell(k,v) \in [K^2] \) for which \( v \in S_{k,\ell} \). In particular, every \( v \in V(G) \) belongs to exactly \( K \) sets \( S_{k,\ell} \).

Second, observe that by Chernoff’s inequality for a hypergeometrical distribution (see Remark 6), letting \( s = \lfloor n/K^2 \rfloor \), with probability \( 1 - nK^3e^{-\omega \log n} = 1 - o(1) \) we have

\[
d^+_{D}(v,S_{k,\ell}) = |S_{k,\ell}| \pm 4\sqrt{s \log n} \quad \text{and} \quad d^+_{G}(v,S_{k,\ell}) = d^+_{G}(v)/n \pm 4\sqrt{s \log n} \\
\tag{8}
\]

for all \( v \in V(G) \), \( k \in [K] \) and \( \ell \in [K^2] \). In particular, as \( |S_{k,\ell}| = s \pm 1 > n/2K^2 \Rightarrow \log n \), for all \( k \) and \( \ell \) we have

\[
d^+(G[S_{k,\ell}]) \geq \beta|S_{k,\ell}| - 4\sqrt{s \log n} \geq (\beta - \varepsilon/2)|S_{k,\ell}|. \\
\tag{9}
\]

For each \( v \in V(G) \) and \( k \in [K] \), let \( X^+(v,k) \) denote the random variable which counts the number of \( w \in N^+_G(v) \) such that \( w \in S_{k,\ell(k,v)} \cap S_{k',\ell(k',v)} \) for some \( k' \neq k \). Define \( X^-(v,k) \) similarly.

Note that for \( \sigma \in \{+, -\} \) we have

\[
\mathbb{E}[X^\sigma(v,k)] \leq K \left( \frac{n}{K^4} \right) = \frac{n}{K^3} = o(s).
\]

By Chernoff’s inequality, with probability \( 1 - Kne^{-\Theta(n/K^3)} = 1 - o(1) \), for all \( k \in [K] \) and \( v \in V(G) \) we have

\[
X^\sigma(v,k) \leq \frac{2n}{K^3} = o(s). \\
\tag{10}
\]

Lastly, for \( \sigma \in \{+, -\} \) and \( v \in V(D) \) we define the random variable \( Y^\sigma(v) \) to be the set of all vertices \( u \in N^\sigma_D(v) \) with \( u \in S_{k,\ell(k,v)} \) for some \( k \). For all \( \sigma \in \{+, -\} \) and \( v \in V(D) \) we have

\[
b := \mathbb{E}[Y^\sigma(v)] \leq Ks.
\]

Note that, since all the vertices of \( D \) have the same in/outdegrees, the value of \( \mathbb{E}[Y^\sigma(v)] \) is indeed independent of \( v \). By Chernoff’s inequality, with probability \( 1 - 2nKe^{-(2\sqrt{Ks \log n})^2/Ks} = 1 - o(1) \), for all \( \sigma \in \{+, -\} \) and \( v \in V(D) \) we have

\[
Y^\sigma(v) = b \pm 2\sqrt{Ks \log n}. \\
\tag{11}
\]

Thus, with positive probability a collection of partitions satisfy (8), (10) and (11). Fix such a collection. We relabel \( \{S_{k,\ell} \mid k \in [K] \text{ and } \ell \in [K^2]\} \) as \( \{W_1, \ldots, W_K\} \) (arbitrarily). Also set \( F_i = G[W_i] \setminus R_i \), where \( R_i \) is the set of all edges which appear in more than one \( W_i \). From (9) and (10), for each \( i \in [K] \) we obtain

\[
\delta^0(F_i) \geq (\beta - \varepsilon)|W_i|.
\]

Next, let \( D' = D \setminus (\bigcup_i E(G[W_i])) \). As \( D \) is \( d \)-regular, by (11), we have that for all \( \sigma \in \{+, -\} \) and \( v \in V(D) \)

\[
d^\sigma_{D'}(v) = d^\sigma_{D}(v) - Y^\sigma(v) = d - b \pm 2\sqrt{Ks \log n}.
\]

To complete the proof we partition the edges of \( D' \) into further oriented subgraphs

\[
\{D_i\}_{i \in [K^3]} \text{ and } \{E_i\}_{i \in [K^3]}.
\]
Finally, taking $H_i = D_i \cup E_i \cup F_i$ for each $i \in [K^3]$, it is easy to check that these graphs satisfy the requirements.

\[ \square \]

## 6 Proof of Theorem 4

We are now ready to complete the proof of Theorem 4.

**Proof of Theorem 4.** Let $G$ be an oriented graph as in the assumptions of the theorem. Let $d := \text{reg}(G) = \alpha n$ and let $D \subseteq G$ be a $d$-factor of $G$. From Theorem 11, we find that $G$ contains $(c - 3/8)n$ edge disjoint Hamilton cycles, and so $\alpha \geq c - 3/8 > 0$.

First, we apply Lemma 26 to $G$ and $D$, with $\beta = c$, $\alpha$ and $\varepsilon/4$ in place of $\varepsilon$. Setting $K = \log n$, this gives edge-disjoint subgraphs $H_1, \ldots, H_{K^3}$ of $G$ with the following properties:

1. For each $H_i$ there is a partition $V(G) = U_i \cup W_i$ with $|W_i| = n/K^2 \pm 1$;  
2. Letting $D_i = H_i[U_i]$, for some $r \geq (1 - \varepsilon/2)d/K^3$, we have  
\[ r - r^{3/5} \leq \delta^0(D_i) \leq \Delta^0(D_i) \leq r + r^{3/5}, \]
3. Letting $E_i = H_i[U_i, W_i]$ we have $d_{E_i}^+(u, W_i) \geq \varepsilon|W_i|/4K$ for all $u \in U_i$;  
4. Letting $F_i = H_i[W_i]$ we have $\delta^0(F_i) \geq (\beta - \varepsilon)|W_i|$;  

Secondly, by property 2. above we can apply Lemma 18 to each oriented graph $D_i$. This gives $P_i \in \mathcal{P}(D_i, n/\log^4 n, r - n/\log^4 n)$ which satisfies  
\[ \delta^0(D_{P_i}) \geq r - n/\log^4 n. \] (12)
Lastly, apply Lemma 17 to $P_i$ for each $i$. Taking $t = r - n/\log^4 n$ and $a = b = n/\log^4 n$ and $s = |W_i| = n/K^2 \pm 1$, it is easy to check that the conditions of Lemma 17 hold using (12) and properties 3. and 4. above. This gives a collection $C_i := \{C_{i1}, \ldots, C_{it}\}$ of edge-disjoint Hamilton cycles in $H_i$.

To complete the proof, set $C := \bigcup_i C_i$. Since the $H_i$ are edge-disjoint, together with property 3., we find that $C$ consists of $K^3 t \geq (1 - \varepsilon/2) K^3 r \geq (1 - \varepsilon) d$

edge-disjoint Hamilton cycles of $G$. This completes the proof.

\[ \square \]

7 Proof of Theorem 2

Before proving Theorem 2 let us introduce a final convenient definition.

Definition 27. Given an oriented graph $H$, a collection of $t$ edge-disjoint Hamilton cycles $\{C_1, \ldots, C_t\}$ of $G$ is called an $(H, t)_C$-family. Let $C(H, t)$ denote the set of all $(H, t)_C$-families of $H$.

We are now ready for the proof of Theorem 2.

Proof of Theorem 2. Let $c > 3/8$ be fixed and $d = cn$. We would like to show that given any $\varepsilon > 0$ and a large enough $n$, every $d$-regular oriented graph $G$ on $n$ vertices satisfies

\[ |C(G, d)| \geq n(1 - \varepsilon)dn. \]

Let $K = \log n$ and $\alpha = \varepsilon/4$. Our proof proceeds in five steps.

Step 1. Removing a $\delta$-absorbing subgraph from $G$.

By Theorem 14, there exists $\delta > 0$ such that $G$ contains a $\delta$-absorber subgraph $A$, where $A$ is $\alpha$-regular, with $\alpha \leq \alpha n$. Fix such a choice of $A$ and let $G_0 := G \setminus A$.

Step 2. Partitioning $G_0$.

Note that $G_0$ is $d' := cn - \alpha$ regular with $\beta := d'/n > 3/8$. Therefore, taking $D = G$ and $\varepsilon_0 = \varepsilon/10$, applying Lemma 26, one can find $K^3$ edge-disjoint spanning subgraphs $H_1, \ldots, H_{K^3}$ of $G_0$ satisfying:

1. For each $H_i$ there is a partition $V(G) = U_i \cup W_i$ with $|W_i| = n/K^2 \pm 1$;
2. Letting $D_i = H_i[U_i]$, with $r \geq (1 - 2\varepsilon_0)d'/K^3$, we have
   \[ r - r^{3/5} \leq \delta^0(D_i) \leq \Delta^0(D_i) \leq r + r^{3/5}; \]
3. Letting $E_i = H_i[U_i, W_i]$ we have $d_{E_i}^+(u, W_i) \geq \varepsilon_0|W_i|/4K$ for all $u \in U_i$;
4. Letting $F_i = H_i[W_i]$ we have $\delta^0(F_i) \geq (\beta - \varepsilon_0)|W_i|$.

Step 3. Showing that for some $t = r - o(r)$ and for every $i \in [K^3]$ the set $C(H_i, t)$ is large.
To this end, let us first apply Lemma 18 to each of the $D_i$s (note that by Property 3 above, the assumptions are fulfilled, and that $|U_i| = m = (1-o(1))n$). It thus follows that for every $i$ we have a collection

$$ \mathcal{P}_i \subseteq \mathcal{P}(D_i, n/\log^4 n, r - n/\log^4 n) $$

which satisfies

$$ |\mathcal{P}_i| \geq r^{(1-o(1))rn}, $$

such that $\delta^0(D_{\mathcal{P}_i}) \geq r - n/\log^4 n$ for all $\mathcal{P}_i \in \mathcal{P}_i$.

Therefore, by Properties 4, 5 and the lower bound on $\delta^0(D_{\mathcal{P}_i})$, the hypothesis of Lemma 17 apply to $H_i$ and $\mathcal{P}_i$, taking $a = b = n/\log^4 n$, $t = r - n/\log^4 n$ and $s = |W_i| = n/K^2 \pm 1$. This lemma allows us to turn $\mathcal{P}_i$ into a collection of $t = r - n/\log^4 n$ edge-disjoint Hamilton cycles. Noting that we fix the $W_i$ sets throughout the proof, we can trivially recover the path cover used to build each of the cycles. Therefore, for all $i \in [K^3]$ we have

$$ |\mathcal{C}(H_i, t)| \geq |\mathcal{P}_i| \geq r^{(1-o(1))rn}. \tag{13} $$

**Step 4.** Showing that $G_0$ has $n^{(1-\varepsilon)dn}$ ‘almost Hamilton decompositions’.

To see this, note that if we pick $C_i \in \mathcal{C}(H_i, t)$ for all $i$, then $C = \bigcup_i C_i \in \mathcal{C}(G_0, K^3t)$. Therefore, by (13), for $t' = K^3t$ we conclude that

$$ |\mathcal{C}(G_0, t')| \geq r^{(1-o(1))rnK^3} \geq d^{(1-\varepsilon/5)d'\alpha n} \geq n^{(1-\varepsilon/4)(1-\alpha)dn} \geq n^{(1-\varepsilon/2)dn}. \tag{14} $$

**Step 5.** Completing every $C \in \mathcal{C}(G_0, t')$ to a Hamilton decomposition of $G$.

Let $C \in \mathcal{C}(G_0, t')$ and note that $G' = G_0 \setminus C$ is a $b$-regular oriented graph with $b = o(n)$. Since $A := G \setminus G_0$ is a $\delta$-absorber, and $b < \delta n$, it follows from Theorem 14 that $A \cup G'$ has a Hamilton decomposition $C'$. But then $C \cup C'$ is a Hamilton decomposition of $G$. Lastly, note that although different choices of $C \in \mathcal{C}(G_0, t')$ may give rise to the same Hamilton decomposition in this way, it is easy to see that each such decomposition occurs at most $\binom{n}{d'} \leq 2^n$ times. By (14), this gives

$$ |\mathcal{C}(G, d)| \geq |\mathcal{C}(G_0, t')|/2^n \geq n^{(1-\varepsilon)dn}. $$

This completes the proof. \qed

### 8 Concluding remarks

In this paper we have given bounds on the number of Hamilton decompositions of dense regular oriented graphs. Theorem 4 shows that if $G$ is an $r$-regular $n$-vertex oriented graph, with $r = cn$ for some fixed $c > 3/8$, then it has $r^{(1+o(1))rn}$ Hamilton decompositions. As indicated in the Introduction this bound is tight for every such graph, up to the $o(1)$-term in the exponent.

We believe that such oriented graphs should in fact have $\left( (1 + o(1)) \frac{n}{r} \right)^{rn}$ Hamilton decompositions. This would agree with the more precise upper bound obtained from the Minc conjecture in the Introduction. To prove this seems to require a version of Theorem 14 which can be applied to oriented graphs with sublinear density. In this respect, it would be very interesting to obtain an alternative proof of Kelly’s conjecture that does not make use of regularity, as it seems likely to lead to such a theorem.
