#### Abstract

We prove that for a 3-monotone function $F \in C[-1,1]$, one can achieve the pointwise estimates $$
|F(x)-\Psi(x)| \leq c \omega_{3}\left(F, \rho_{n}(x)\right), \quad x \in[-1,1],
$$ where $\rho_{n}(x):=\frac{1}{n^{2}}+\frac{\sqrt{1-x^{2}}}{n}$ and $c$ is an absolute constant, both with $\Psi$, a 3-monotone quadratic spline on the $n$th Chebyshev partition, and with $\Psi$, a 3-monotone polynomial of degree $\leq n$.

The basis for the construction of these splines and polynomials is the construction of 3-monotone splines, providing appropriate order of pointwise approximation, half of which nodes are prescribed and the other half are free, but "controlled". © 2012 Elsevier Inc. All rights reserved.

Keywords: Shape preserving approximation; 3-monotone approximation by piecewise polynomials and splines; 3-monotone polynomial approximation; Degree of pointwise approximation

## 1. Introduction and historical background

In recent years there has been much interest and there have been quite a few achievements in questions concerning the degree of approximation of a continuous function $f$, on a finite

[^0]interval, which has a certain shape, by algebraic polynomials and by piecewise polynomials possessing the same shape. By shape we mean nonnegativity, monotonicity, convexity and higher order monotonicity ( $q$-monotonicity), and finitely many changes in one of the above shapes in the interval (e.g., $f$ may be nondecreasing and nonincreasing, alternately, or $f$ may be convex and concave, alternately, finitely many times). Estimates on the degree of approximation are either given in the uniform norm, usually involving various moduli of smoothness of $f$ or its derivatives (provided they exist), or are pointwise estimates. Much is known about the degree of positive, monotone and convex approximation and a lot is known on the degree of $q$-monotone approximation where $q \geq 4$ (mostly negative results), but relatively little is known about the degree of 3-monotone approximation. The interested reader can find details in the recent survey [7].

We begin with the basic notions and the known results on 3-monotone approximation.
Let $n \in \mathbb{N}$. Throughout the paper $x_{j}:=\cos \frac{j \pi}{n}, j=0, \ldots, n$, will denote the Chebyshev knots, and $-1=x_{n}<x_{n-1}<\cdots<x_{1}<x_{0}=1$, the Chebyshev partition. Set $I_{j}:=\left[x_{j}, x_{j-1}\right], j=1, \ldots, n$, and $\left|I_{j}\right|=x_{j-1}-x_{j}$. Finally, for $x \in[-1,1]$, let

$$
\rho_{n}(x):=\frac{1}{n^{2}}+\frac{\sqrt{1-x^{2}}}{n} .
$$

Let $\mathcal{P}_{n}$ denote the space of algebraic polynomials of degree $<n$. Denote by $\Delta^{3}=\Delta^{3}[-1,1]$ the set of 3 -monotone continuous functions on $[-1,1]$, i.e., $f \in \Delta^{3}$, if $f \in C[-1,1]$ and $f^{\prime}$ exists and is convex in $(-1,1)$. For $f \in \Delta^{3}$ we denote the degree of 3-monotone polynomial approximation by

$$
E_{n}^{(3)}(f):=\inf _{P_{n} \in \mathcal{P}_{n} \cap \Delta^{3}}\left\|f-P_{n}\right\|,
$$

where the norm is the uniform norm on $[-1,1]$.
It was proved by Beatson [1] (for $k=1$ ), Shvedov [11] (for $k=2$ ), and Bondarenko [2] (for $k=3$ ), that

$$
\begin{equation*}
E_{n}^{(3)}(f) \leq c \omega_{k}(f, 1 / n), \quad n \geq N \tag{1.1}
\end{equation*}
$$

where $c$ is an absolute constant, independent of $f$ and $n$, and $N=k$ for $k=1,2$ and 3 , respectively.

We remind the reader that for $g \in C[-1,1]$ and $k \geq 1$,

$$
\begin{equation*}
\omega_{k}(g, \delta):=\sup _{|h| \leq \delta}\left\|\Delta_{h}^{k}(g, \cdot)\right\|, \quad \delta>0 \tag{1.2}
\end{equation*}
$$

where

$$
\Delta_{h}^{k}(g, x):= \begin{cases}\sum_{i=0}^{k}\binom{k}{i}(-1)^{k-i} g\left(x+\left(\frac{k}{2}-i\right) h\right), & \text { if } x \pm k h / 2 \subseteq[-1,1]  \tag{1.3}\\ 0, & \text { otherwise }\end{cases}
$$

Furthermore, Shvedov [12] proved that for $k>4$, (1.1) cannot be had with $c=c(k)$ and $N=N(k)$ (constants which depend on $k$ ), and Wu and Zhou [13] proved that for $k>5$, (1.1) cannot be had even with $c=c(f)$ and $N=N(f)$. Still nothing is known for $k=4$.

In the case of 3-monotone piecewise polynomial approximation we shall limit ourselves to the uniform and the Chebyshev partition of $[-1,1]$. The first estimate is due to Konovalov and

Leviatan [5], who proved that given $f \in \Delta^{3} \cap C^{2}[-1,1]$, there exists a quadratic spline $S \in \Delta^{3}$, with $n$ equidistant nodes in $[-1,1]$ (the uniform partition), such that

$$
\|f-S\| \leq \frac{c}{n^{2}} \omega_{1}\left(f^{\prime \prime}, 1 / n\right), \quad n \geq 1
$$

where $c$ is an absolute constant. This was extended by Prymak [10] who proved for $f \in \Delta^{3}$, the existence of a piecewise quadratic $S \in \Delta^{3}$, with $n$ equidistant nodes in $[-1,1]$, such that

$$
\|f-S\| \leq c \omega_{3}(f, 1 / n), \quad n \geq 1
$$

(In fact Prymak [10] has obtained estimates involving the third modulus of smoothness of $f$ for the approximation by 3 -monotone piecewise quadratics on an arbitrary partition of $[-1,1]$.)

In 2005 Leviatan and Prymak [8] proved that most of the expected Jackson type norm estimates are valid for 3-monotone piecewise polynomial approximation. Namely, given $f \in$ $\Delta^{3} \cap C^{r}[-1,1]$, where either $r \geq 3$ and $k \geq 1$, or $r=1,2$ and $k=4-r$, there exist piecewise polynomials $S_{1}, S_{2} \in \Delta^{3}$, of degree $\leq k+r-1$, such that $S_{1}$ has $n$ equidistant nodes and $S_{2}$ has nodes on the Chebyshev partition, and which satisfy

$$
\left\|f-S_{1}\right\| \leq \frac{c(k, r)}{n^{r}} \omega_{k}\left(f^{(r)}, 1 / n\right)
$$

and

$$
\left\|f-S_{2}\right\| \leq \frac{c(k, r)}{n^{r}} \omega_{k}^{\varphi}\left(f^{(r)}, 1 / n\right)
$$

where $\omega_{k}^{\varphi}$ is the $k$ th Ditzian-Totik (D-T) modulus of smoothness. Namely, for $g \in C[-1,1]$ and $k \geq 1$,

$$
\omega_{k}^{\varphi}(g, \delta):=\sup _{0<h \leq \delta}\left\|\Delta_{h \varphi(\cdot)}^{k}(g, \cdot)\right\|, \quad \delta>0
$$

where $\Delta_{h}^{k}$ is defined in (1.3) and $\varphi(x):=\sqrt{1-x^{2}}, x \in[-1,1]$.
Recently Dzyubenko et al. [4] have closed the gap by proving the only remaining open case, $k=4$ and $r=0$, namely, there exist splines $S_{1}, S_{2} \in \Delta^{3}$, of degree $\geq 3$, such that $S_{1}$ has $n$ equidistant nodes and $S_{2}$ has nodes on the Chebyshev partition, and which satisfy

$$
\left\|f-S_{1}\right\| \leq c \omega_{4}(f, 1 / n)
$$

and

$$
\left\|f-S_{2}\right\| \leq c \omega_{4}^{\varphi}(f, 1 / n)
$$

Since the purpose of this paper is to establish pointwise estimates involving the third modulus of smoothness for 3-monotone approximation of $f \in \Delta^{3}$ by both 3-monotone polynomials and quadratic splines on the Chebyshev partition, it is worthwhile mentioning the negative result of Bondarenko and Gilewicz [3], who proved that for $r>4$, there exists a constant $c=c(r)>0$, such that for each $n \in \mathbb{N}$, there is an $f=f_{n} \in \Delta^{3} \cap C^{r}[-1,1],\left\|f^{(r)}\right\| \leq 1$, such that for every polynomial $P_{n} \in \mathcal{P}_{n} \cap \Delta^{3}$, there is an $x \in[-1,1]$ for which

$$
\left|f_{n}(x)-P_{n}(x)\right|>c \sqrt{n} \rho_{n}^{r}(x) .
$$

Note that while for monotone and convex approximation by polynomials we cannot have estimates involving the third and fourth moduli of smoothness (of the function), respectively,
we do have estimates involving higher moduli of the derivatives, provided they exist. The above mentioned negative result shows us that we cannot expect similar results for pointwise 3-monotone approximation, at least not for $r>4$.

## 2. The main results

As mentioned above we have the interval $[-1,1]$ and the Chebyshev partition $-1=x_{n}<$ $x_{n-1}<\cdots<x_{1}<x_{0}=1$. When we refer to an arbitrary partition of an arbitrary interval [ $a, b$ ], we will use the notation $a=: \tau_{n}<\tau_{n-1}<\cdots<\tau_{1}<\tau_{0}:=b$, and we will denote by $\Delta^{3}\left[\tau_{n}, \tau_{0}\right]$, the 3 -monotone continuous functions on $\left[\tau_{n}, \tau_{0}\right]$. We will also need the notation $\Delta^{2}\left(\tau_{n}, \tau_{0}\right)$, for the set of all convex continuous functions on $\left(\tau_{n}, \tau_{0}\right)$.

Theorem 1. Let $\tau_{n}<\cdots<\tau_{1}<\tau_{0}$ be given and let $F \in \Delta^{3}\left[\tau_{n}, \tau_{0}\right]$ be a function with a derivative $f:=F^{\prime} \in \Delta^{2}\left(\tau_{n}, \tau_{0}\right)$. Suppose, that $s \in \Delta^{2}\left(\tau_{n}, \tau_{0}\right)$ is a piecewise polynomial of order $k$ (degree $k-1$ ) with nodes $\tau_{n}, \ldots, \tau_{1}, \tau_{0}$, satisfying

$$
\begin{aligned}
& s\left(\tau_{i}\right)=f\left(\tau_{i}\right), \quad i=0, \ldots, n \\
& s^{\prime}\left(\tau_{i}+\right) \geq f^{\prime}\left(\tau_{i}+\right), \quad i=1, \ldots, n \\
& f^{\prime}\left(\tau_{i}-\right) \geq s^{\prime}\left(\tau_{i}-\right), \quad i=0, \ldots, n-1
\end{aligned}
$$

Then, there are at most $n$ additional nodes $\theta_{n}, \ldots, \theta_{1}$, such that $\tau_{n}<\theta_{n}<\tau_{n-1}<\theta_{n-1}<$ $\tau_{n-2}<\cdots<\theta_{1}<\tau_{0}$, and a piecewise polynomial $S \in \Delta^{3}\left[\tau_{n}, \tau_{0}\right]$ of order $k+1$ with the nodes $\tau_{n}, \theta_{n}, \tau_{n-1}, \ldots, \theta_{1}, \tau_{0}$, satisfying

$$
\begin{equation*}
\|F-S\|_{C\left[\tau_{i}, \tau_{i-1}\right]} \leq 2\left\|\int_{\tau_{i}}^{(\cdot)}(f(x)-s(x)) d x\right\|_{C\left[\tau_{i}, \tau_{i-1}\right]}, \quad i=1, \ldots, n, \tag{2.1}
\end{equation*}
$$

and such that

$$
\begin{equation*}
F\left(\tau_{i}\right)=S\left(\tau_{i}\right), \quad i=0, \ldots, n \tag{2.2}
\end{equation*}
$$

We are now able to state the pointwise estimates for 3-monotone approximation.
We begin with the splines.
Theorem 2. For each function $F \in \Delta^{3}$ and every $n \geq 1$, there exists a quadratic spline $S \in \Delta^{3}$ on the Chebyshev partition $-1=x_{n}<\cdots<x_{1}<x_{0}=1$, satisfying

$$
\begin{equation*}
|F(x)-S(x)| \leq c \omega_{3}\left(F, \rho_{n}(x)\right), \quad x \in[-1,1] \tag{2.3}
\end{equation*}
$$

where $c$ is an absolute constant.
For the polynomials we have the following theorem.
Theorem 3. For each function $F \in \Delta^{3}$ and every $n \geq 2$, there exists a polynomial $P_{n} \in \Delta^{3}$ of degree $\leq n$, satisfying

$$
\begin{equation*}
\left|F(x)-P_{n}(x)\right| \leq c \omega_{3}\left(F, \rho_{n}(x)\right), \quad x \in[-1,1] \tag{2.4}
\end{equation*}
$$

where $c$ is an absolute constant.
The next section is devoted to the proof of Theorem 1. Then we need quite a few lemmas, in Sections 4 and 5, before we are able to prove Theorem 2 in Section 6. Finally, in Section 7, we replace the 3-monotone quadratic spline we construct in Section 6, by a 3-monotone polynomial.

In the sequel $c$ denotes a generic constant which may differ at each occurrence.

## 3. Splines with controlled nodes

Theorem 1 is an easy consequence of the following lemma, which is a modification of Lemma 1 from [8].

Lemma 1. Let $f, g, f_{1}, f_{2}$ be continuous functions on $[a, b]$, and such that

$$
f_{1}(x) \leq f(x), g(x) \leq f_{2}(x), \quad x \in[a, b] .
$$

Then, there are coefficients $\alpha, \alpha_{1}, \alpha_{2} \geq 0$, with $\alpha+\alpha_{1}+\alpha_{2}=1$, such that

$$
h(x):=\alpha g(x)+\alpha_{1} f_{1}(x)+\alpha_{2} f_{2}(x), \quad x \in[a, b]
$$

## satisfies

$$
\begin{aligned}
& \int_{a}^{b} f(x) d x=\int_{a}^{b} h(x) d x \\
& \left\|\int_{a}^{(\cdot)}(h(x)-f(x)) d x\right\|_{C[a, b]} \leq 2\left\|\int_{a}^{(\cdot)}(g(x)-f(x)) d x\right\|_{C[a, b]}
\end{aligned}
$$

Proof. If $\int_{a}^{b} f(x) d x=\int_{a}^{b} g(x) d x$, then take $h(x):=g(x), x \in[a, b]$, namely, $\alpha=1$ and $\alpha_{1}=\alpha_{2}=0$, and there is nothing to prove. Otherwise, if $\int_{a}^{b} f(x) d x>\int_{a}^{b} g(x) d x$, then we apply the arguments of proof of Lemma 1 in [8] with $g$ replacing $q$ and $f_{2}$ replacing $l$. The resulting function is the convex combination of $g$ and $f_{2}$, namely, $\alpha_{1}:=0$, and $\alpha, \alpha_{2}$ are defined by the corresponding formula from [8]. On the other hand, if $\int_{a}^{b} f(x) d x<\int_{a}^{b} g(x) d x$, then we apply similar arguments, which we detail here and which will serve also as a reminder of the proof in [8]. Thus, assume that $\int_{a}^{b} f(x) d x<\int_{a}^{b} g(x) d x$, and denote

$$
\int_{a}^{b}(g(x)-f(x)) d x=: A>0
$$

and

$$
\int_{a}^{b}\left(f(x)-f_{1}(x)\right) d x=: B \geq 0
$$

Set

$$
h(x):=\frac{A f_{1}(x)+B g(x)}{A+B}
$$

Now,

$$
\begin{aligned}
\left|\int_{a}^{x}(h(t)-f(t)) d t\right| \leq & \frac{A}{A+B}\left|\int_{a}^{x}\left(f_{1}(t)-f(t)\right) d t\right| \\
& +\frac{B}{A+B}\left|\int_{a}^{x}(g(t)-f(t)) d t\right| \\
\leq & \frac{A B}{A+B}+\frac{B}{A+B}\left\|\int_{a}^{x}(g(t)-f(t)) d t\right\|_{C[a, b]}
\end{aligned}
$$

$$
\begin{aligned}
& \leq \frac{2 B}{A+B}\left\|\int_{a}^{x}(g(t)-f(t)) d t\right\|_{C[a, b]} \\
& \leq 2\left\|\int_{a}^{x}(g(t)-f(t)) d t\right\|_{C[a, b]}
\end{aligned}
$$

Finally,

$$
\begin{aligned}
\int_{a}^{b} h(x) d x & =\frac{A}{A+B} \int_{a}^{b} f_{1}(x) d x+\frac{B}{A+B} \int_{a}^{b} g(x) d x \\
& =\frac{A}{A+B}\left(B+\int_{a}^{b} f_{1}(x) d x\right)+\frac{B}{A+B}\left(-A+\int_{a}^{b} g(x) d x\right) \\
& =\int_{a}^{b} f(x) d x
\end{aligned}
$$

This concludes the proof.
Proof of Theorem 1. Let $i=1, \ldots, n$ be fixed. Put

$$
\begin{aligned}
f_{1}(x):= & \max \left\{f^{\prime}\left(\tau_{i}+\right)\left(x-\tau_{i}\right)+f\left(\tau_{i}\right), f^{\prime}\left(\tau_{i-1}-\right)\left(x-\tau_{i-1}\right)+f\left(\tau_{i-1}\right)\right\}, \\
& x \in\left[\tau_{i}, \tau_{i-1}\right],
\end{aligned}
$$

and

$$
f_{2}(x):=\frac{f\left(\tau_{i}\right)\left(x-\tau_{i-1}\right)}{\tau_{i}-\tau_{i-1}}+\frac{f\left(\tau_{i-1}\right)\left(x-\tau_{i}\right)}{\tau_{i-1}-\tau_{i}}, \quad x \in\left[\tau_{i}, \tau_{i-1}\right]
$$

Then $f_{2}$ is a linear function, and $f_{1}$ is a piecewise-linear function with one node $\theta_{i} \in\left(\tau_{i}, \tau_{i-1}\right)$. Moreover, the construction of $f_{1}$ and $f_{2}$ and well known properties of convex functions yield that if $\tilde{f}$ is a convex function on $\left[\tau_{i}, \tau_{i-1}\right]$, satisfying

$$
\begin{aligned}
& \tilde{f}\left(\tau_{i}\right)=f\left(\tau_{i}\right), \quad \tilde{f}\left(\tau_{i-1}\right)=f\left(\tau_{i-1}\right), \\
& \tilde{f}^{\prime}\left(\tau_{i}+\right) \geq f^{\prime}\left(\tau_{i}+\right) \quad \text { and } \quad \tilde{f}^{\prime}\left(\tau_{i-1}-\right) \leq f^{\prime}\left(\tau_{i-1}-\right),
\end{aligned}
$$

then

$$
f_{1}(x) \leq \tilde{f}(x) \leq f_{2}(x), \quad x \in\left[\tau_{i}, \tau_{i-1}\right] .
$$

Hence,

$$
f_{1}(x) \leq f(x) \leq f_{2}(x), \quad x \in\left[\tau_{i}, \tau_{i-1}\right]
$$

and

$$
f_{1}(x) \leq s(x) \leq f_{2}(x), \quad x \in\left[\tau_{i}, \tau_{i-1}\right]
$$

By virtue of Lemma 1, we have a function

$$
h_{i}(x):=\alpha s(x)+\alpha_{1} f_{1}(x)+\alpha_{2} f_{2}(x), \quad x \in\left[\tau_{i}, \tau_{i-1}\right]
$$

such that $\alpha, \alpha_{1}, \alpha_{2} \geq 0$, and $\alpha+\alpha_{1}+\alpha_{2}=1$, which is a convex piecewise polynomial of order $k$ with at most one node $\theta_{i} \in\left(\tau_{i}, \tau_{i-1}\right)$, and satisfies

$$
\begin{equation*}
\int_{\tau_{i}}^{\tau_{i-1}} h_{i}(x) d x=\int_{\tau_{i}}^{\tau_{i-1}} f(x) d x \tag{3.1}
\end{equation*}
$$

and

$$
\begin{equation*}
\left\|\int_{\tau_{i}}^{(\cdot)}\left(h_{i}(x)-f(x)\right) d x\right\|_{C\left[\tau_{i}, \tau_{i-1}\right]} \leq 2\left\|\int_{\tau_{i}}^{(\cdot)}(s(x)-f(x)) d x\right\|_{C\left[\tau_{i}, \tau_{i-1}\right]} . \tag{3.2}
\end{equation*}
$$

Note, that the construction of $h_{i}$ gives

$$
h_{i}\left(\tau_{i}\right)=h_{i+1}\left(\tau_{i}\right), \quad i=1, \ldots, n-1,
$$

and

$$
h_{i+1}^{\prime}\left(\tau_{i}\right) \leq f^{\prime}\left(\tau_{i}-\right) \leq f^{\prime}\left(\tau_{i}+\right) \leq h_{i}^{\prime}\left(\tau_{i}\right), \quad i=1, \ldots, n-1,
$$

so that the function

$$
h(x):=h_{i}(x), \quad x \in\left[\tau_{i}, \tau_{i-1}\right], i=1, \ldots, n,
$$

is a piecewise polynomial of order $k$ with the nodes $\tau_{n}, \ldots, \tau_{0}$ and, perhaps, some additional nodes (with at most one node $\theta_{i} \in\left(\tau_{i}, \tau_{i-1}\right), i=1, \ldots, n$ ), moreover $h \in \Delta^{2}\left[\tau_{n}, \tau_{0}\right]$.

Finally, let

$$
S(x):=\int_{\tau_{n}}^{x} h(t) d t+F\left(\tau_{n}\right), \quad x \in\left[\tau_{n}, \tau_{0}\right] .
$$

Then, (2.2) readily follows (3.1), whence, in turn, (2.1) follows by virtue of (3.2). This completes the proof.

## 4. A fundamental lemma

We will need the following relations between the lengths of the various intervals $I_{j}$, and between these lengths and $\rho_{n}(x), x \in I_{j}$. The following relations are well known (see, e.g., [9, (1.2) and (1.3)]).

$$
\begin{equation*}
\rho_{n}(x)<\left|I_{j}\right|<5 \rho_{n}(x), \quad x_{j} \leq x \leq x_{j-1}, j=1, \ldots, n \tag{4.1}
\end{equation*}
$$

so that, in particular

$$
\begin{equation*}
\rho_{n}\left(x_{j-1}\right)<5 \rho_{n}\left(x_{j}\right), \quad j=1, \ldots, n . \tag{4.2}
\end{equation*}
$$

Also

$$
\begin{equation*}
\left|I_{j \pm 1}\right|<3\left|I_{j}\right|, \quad j=1, \ldots, n \tag{4.3}
\end{equation*}
$$

where we put $\left|I_{n+1}\right|=\left|I_{0}\right|=0$, and it is easy to see that for $j>i$,

$$
\begin{equation*}
\max \left\{\left|I_{j}\right|,\left|I_{i}\right|\right\} \frac{j-i}{3 \pi} \leq x_{i}-x_{j} \tag{4.4}
\end{equation*}
$$

Finally, for all $x \in[-1,1]$ and every $1 \leq j \leq n-1$

$$
\begin{equation*}
\rho_{n}^{2}(x) \leq c \rho_{n}\left(x_{j}\right)\left(\rho_{n}\left(x_{j}\right)+\left|x-x_{j}\right|\right) \tag{4.5}
\end{equation*}
$$

and, symmetrically,

$$
\begin{equation*}
\rho_{n}^{2}\left(x_{j}\right) \leq c \rho_{n}(x)\left(\rho_{n}(x)+\left|x-x_{j}\right|\right) \tag{4.6}
\end{equation*}
$$

where $c$ is an absolute constant.

Lemma 2. Given numbers $\alpha_{j} \in[0,1], j=1, \ldots$, M. If

$$
\begin{equation*}
\sum_{j=1}^{M} \alpha_{j} \geq S, \quad S \in \mathbb{N} \tag{4.7}
\end{equation*}
$$

then

$$
\begin{equation*}
\sum_{j=1}^{M} j \alpha_{j} \geq \sum_{j=1}^{S} j \tag{4.8}
\end{equation*}
$$

Proof. Since $\alpha_{j} \leq 1, j=1, \ldots, M$, it follows from (4.7) that for each $K=1, \ldots, S$ that

$$
\sum_{j=K}^{M} \alpha_{j} \geq S-K+1
$$

Thus, adding these inequalities for $K=1, \ldots, S$, we obtain

$$
\alpha_{1}+2 \alpha_{2}+\cdots+S \alpha_{S}+S \alpha_{S+1}+\cdots+S \alpha_{M} \geq \sum_{K=1}^{S}(S-K+1)=\sum_{j=1}^{S} j
$$

which in turn implies (4.8).
The next lemma is a fundamental lemma in our construction.
We require the notation

$$
x_{+}^{0}= \begin{cases}1, & x \geq 0 \\ 0, & x<0\end{cases}
$$

Lemma 3. Let $F \in C[-1,1]$, and let the integers $D$, $s$ and $k$, such that $n / 2 \leq s<k \leq n$, be given. Assume that

$$
g(x)=\sum_{j=s}^{k} \alpha_{j}\left(x-x_{j}\right)_{+}^{0}
$$

is a step function satisfying

$$
\begin{align*}
& 0 \leq \alpha_{j} \leq C \omega_{3}\left(F, \rho_{n}\left(x_{j}\right)\right), \quad j=s, \ldots, k  \tag{4.9}\\
& g\left(x_{s}\right)>200 C D \omega_{3}\left(F, \rho_{n}\left(x_{s}\right)\right),  \tag{4.10}\\
& g\left(x_{l}\right) \leq 200 C D \omega_{3}\left(F, \rho_{n}\left(x_{l}\right)\right), \quad l=s+1, \ldots, k \tag{4.11}
\end{align*}
$$

for some constant $C>0$. Then there exists a nondecreasing polygonal line

$$
S(x)=\sum_{j=s}^{k} \frac{\beta_{j}}{\left|I_{j}\right|}\left(x-x_{j}\right)_{+},
$$

such that

$$
\begin{align*}
& \left|\beta_{j}\right| \leq \frac{\alpha_{j}}{D}  \tag{4.12}\\
& S(x)=g(x), \quad x \in[-1,1] \backslash\left[x_{k}, x_{s}\right],  \tag{4.13}\\
& |g(x)-S(x)| \leq 402 C D \omega_{3}\left(F, \rho_{n}(x)\right), \quad x \in\left[x_{k}, x_{s}\right] . \tag{4.14}
\end{align*}
$$

Remark 1. Note that in view of (4.9) and (4.10), $F \notin \mathcal{P}_{3}$.
Proof. Note that $x_{s} \leq 0$, so that $\rho_{n}\left(x_{s}\right)>\rho_{n}\left(x_{l}\right), l=s+1, \ldots, k$, and let $u, s \leq u \leq k$, be the largest integer such that

$$
\begin{equation*}
\omega_{3}\left(F, \rho_{n}\left(x_{u}\right)\right) \geq \frac{1}{2} \omega_{3}\left(F, \rho_{n}\left(x_{s}\right)\right) \tag{4.15}
\end{equation*}
$$

Then, by (4.11),

$$
\sum_{j=u+1}^{k} \alpha_{j} \leq 200 C D \omega_{3}\left(F, \rho_{n}\left(x_{u+1}\right)\right) \leq 100 C D \omega_{3}\left(F, \rho_{n}\left(x_{s}\right)\right)
$$

Hence, by (4.10)

$$
\sum_{j=s}^{u} \alpha_{j} \geq 100 C D \omega_{3}\left(F, \rho_{n}\left(x_{s}\right)\right)
$$

Denote by $v, s \leq v \leq u$, the largest integer such that

$$
\sum_{j=v+1}^{u} \alpha_{j} \geq 65 C D \omega_{3}\left(F, \rho_{n}\left(x_{s}\right)\right)
$$

Put

$$
p:=\sum_{j=v+1}^{u} \frac{\alpha_{j}}{\left|I_{j}\right|}, \quad q:=\sum_{j=s}^{v} \frac{\alpha_{j}}{\left|I_{j}\right|}, \quad \Lambda:=\frac{p}{q} .
$$

Note that $q \neq 0$, since by the definition of $v$ we have

$$
\sum_{j=s}^{v+1}>35 C D \omega_{3}\left(F, \rho_{n}\left(x_{s}\right)\right)
$$

and by (4.9), $\alpha_{v+1} \leq C \omega_{3}\left(F, \rho_{n}\left(x_{v+1}\right)\right) \leq C \omega_{3}\left(F, \rho_{n}\left(x_{s}\right)\right)$, whence $\sum_{j=s}^{v} \alpha_{j}>0$.
If $\Lambda \leq 1$, then we put

$$
\hat{\beta}_{j}:= \begin{cases}\frac{-\Lambda \alpha_{j}}{\alpha_{j}}, & j=s, \ldots, v, \\ \frac{\alpha_{j}}{D}, & j=v+1, \ldots, u\end{cases}
$$

Otherwise, $\Lambda>1$, and we set

$$
\hat{\beta}_{j}:= \begin{cases}\frac{-\alpha_{j}}{D}, & j=s, \ldots, v, \\ \frac{\alpha_{j}}{\Lambda D}, & j=v+1, \ldots, u\end{cases}
$$

Denote

$$
\begin{equation*}
\beta_{j}:=\hat{\beta}_{j} \frac{g\left(x_{s}\right)}{\sum_{i=s}^{u} \frac{\hat{\beta}_{i}}{\left|I_{i}\right|}\left(x_{s}-x_{i}\right)}, \quad j=s, \ldots, u \tag{4.16}
\end{equation*}
$$

and, finally, put $\beta_{j}:=\hat{\beta}_{j}:=0$, for $j=u+1, \ldots, k$. We will show that the polygonal line

$$
S(x)=\sum_{j=s}^{k} \frac{\beta_{j}}{\left|I_{j}\right|}\left(x-x_{j}\right)_{+}
$$

is the required one. To this end, evidently,

$$
\begin{align*}
& \sum_{j=t}^{k} \frac{\hat{\beta}_{j}}{\left|I_{j}\right|} \geq 0, \quad t=s+1, \ldots, k  \tag{4.17}\\
& \sum_{j=s}^{k} \frac{\hat{\beta}_{j}}{\left|I_{j}\right|}=0 \tag{4.18}
\end{align*}
$$

and

$$
\begin{equation*}
\left|\hat{\beta}_{j}\right| \leq \frac{\alpha_{j}}{D} \tag{4.19}
\end{equation*}
$$

We will prove that

$$
\begin{equation*}
\sum_{j=s}^{k} \frac{\hat{\beta}_{j}}{\left|I_{j}\right|}\left(x_{s}-x_{j}\right)>g\left(x_{s}\right)=\sum_{j=s}^{k} \alpha_{j} \tag{4.20}
\end{equation*}
$$

Indeed, for $\Lambda \leq 1$, by (4.18), (4.4), and Lemma 2, we have

$$
\begin{aligned}
\sum_{j=s}^{k} \frac{\hat{\beta}_{j}}{\left|I_{j}\right|}\left(x_{s}-x_{j}\right) & =\sum_{j=s}^{u} \frac{\hat{\beta}_{j}}{\left|I_{j}\right|}\left(x_{v}-x_{j}\right) \geq \frac{1}{D} \sum_{j=v+1}^{u} \frac{\alpha_{j}}{\left|I_{j}\right|}\left(x_{v}-x_{j}\right) \\
& \geq \frac{1}{3 \pi D} \sum_{j=v+1}^{u} \alpha_{j}(j-v)=\frac{1}{3 \pi D} \sum_{j=1}^{u-v} j \alpha_{j}^{*} \\
& =\frac{C \omega_{3}\left(F, \rho_{n}\left(x_{s}\right)\right)}{3 \pi D} \sum_{j=1}^{u-v} j \frac{\alpha_{j}^{*}}{C \omega_{3}\left(F, \rho_{n}\left(x_{s}\right)\right)} \geq \frac{C \omega_{3}\left(F, \rho_{n}\left(x_{s}\right)\right)}{3 \pi D} \sum_{j=1}^{65 D} j \\
& =\frac{65 D(65 D+1) C \omega_{3}\left(F, \rho_{n}\left(x_{s}\right)\right)}{6 \pi D}>(200 D+1) C \omega_{3}\left(F, \rho_{n}\left(x_{s}\right)\right)
\end{aligned}
$$

where $\alpha_{j}^{*}:=\alpha_{j+v}$, and we used the facts that $0 \leq \alpha_{j}^{*} \leq C \omega_{3}\left(F, \rho_{n}\left(x_{s}\right)\right)$, and

$$
\sum_{j=1}^{u-v} \alpha_{j}^{*}=\sum_{j=v+1}^{u} \alpha_{j} \geq 65 D C \omega_{3}\left(F, \rho_{n}\left(x_{s}\right)\right)
$$

Similarly, if $\Lambda>1$, then we have

$$
\begin{aligned}
\sum_{j=s}^{k} \frac{\hat{\beta}_{j}}{\left|I_{j}\right|}\left(x_{s}-x_{j}\right) & =\sum_{j=s}^{u} \frac{\hat{\beta}_{j}}{\left|I_{j}\right|}\left(x_{v}-x_{j}\right) \\
& \geq \frac{1}{D} \sum_{j=s}^{v} \frac{\alpha_{j}}{\left|I_{j}\right|}\left(x_{j}-x_{v}\right) \\
& >(200 D+1) C \omega_{3}\left(F, \rho_{n}\left(x_{s}\right)\right)
\end{aligned}
$$

On the other hand, the inequalities (4.9) and (4.11) imply

$$
\begin{equation*}
g\left(x_{s}\right) \leq(200 D+1) C \omega_{3}\left(F, \rho_{n}\left(x_{s}\right)\right) \tag{4.21}
\end{equation*}
$$

Hence, (4.20) is proven. Now, (4.12) follows by (4.19) and (4.20), and the definition of $\beta_{j}$, (4.16). Also, (4.16) and (4.17) imply that $S$ is non-decreasing, that $S\left(x_{s}\right)=g\left(x_{s}\right)$, and by virtue of (4.18), we get (4.13). Further, since $S(x)=0, x \leq x_{u}$, (4.11) and (4.21) imply (4.14) for $x \in\left[x_{k}, x_{u}\right]$, where we note that by (4.11), if $x_{l} \leq x<x_{l-1}, l=u, \ldots, k$, then

$$
g(x)=g\left(x_{l}\right) \leq 200 C D \omega_{3}\left(F, \rho_{n}\left(x_{l}\right)\right) \leq 200 C D \omega_{3}\left(F, \rho_{n}(x)\right)
$$

Finally, for $x \in\left[x_{u}, x_{s}\right]$

$$
|S(x)-g(x)| \leq g\left(x_{s}\right)-S\left(x_{u}\right)=g\left(x_{s}\right) \leq(200 D+1) C \omega_{3}\left(F, \rho_{n}\left(x_{s}\right)\right)
$$

by (4.21). Now (4.15) implies (4.14) for $x \in\left[x_{u}, x_{s}\right]$. This completes the proof.
Remark 2. Lemma 3 is stated for the interval $[-1,0]$. The situation is completely symmetric for the interval $[0,1]$ (one only has to take a mirror image of the conditions, this time with $1 \leq k<s \leq n / 2$ ). We leave the statement and proof to the reader. (See also Remark 3.)

Lemma 3 is the main tool we use in the proof of Lemma 7. However, in that proof we may encounter a case where the conditions of Lemma 3 are not satisfied and we need to apply another tool. This is the purpose of the following observation.

Lemma 4. Let $\lceil n / 2\rceil \leq k<n$, and assume that the nonnegative numbers $\alpha_{j}$ are such that

$$
\begin{equation*}
\sum_{j=s}^{k} \alpha_{j} \leq c \omega_{3}\left(F, \rho_{n}\left(x_{s}\right)\right), \quad s=\lceil n / 2\rceil, \ldots, k \tag{4.22}
\end{equation*}
$$

Then for $x_{l} \leq x<x_{l-1}, l=\lceil n / 2\rceil, \ldots, k-1$, and for $-1 \leq x<x_{k-1}$, for $l=k$, we have

$$
\begin{equation*}
\sum_{j=\lceil n / 2\rceil}^{l} \alpha_{j}\left(\frac{1+x}{1+x_{j}}\right)^{2} \leq \tilde{c} \omega_{3}\left(F, \rho_{n}(x)\right) . \tag{4.23}
\end{equation*}
$$

Proof. Denote $m:=\lceil n / 2\rceil$ and let either $x_{l} \leq x<x_{l-1}, l=\lceil n / 2\rceil, \ldots, k-1$, or $-1 \leq x<x_{k-1}$, for $l=k$. We rewrite the left hand side of (4.23) using summation by parts.

$$
\begin{aligned}
\sum_{j=m}^{l} \alpha_{j}\left(\frac{1+x}{1+x_{j}}\right)^{2}= & \sum_{j=m}^{l} \alpha_{j}\left(\frac{1+x}{1+x_{m}}\right)^{2}+\sum_{s=m+1}^{l} \sum_{j=s}^{l} \alpha_{j}(1+x)^{2} \\
& \times\left[\frac{1}{\left(1+x_{s}\right)^{2}}-\frac{1}{\left(1+x_{s-1}\right)^{2}}\right]
\end{aligned}
$$

By virtue of (4.22) we obtain,

$$
\begin{aligned}
\sum_{j=m}^{l} \alpha_{j}\left(\frac{1+x}{1+x_{j}}\right)^{2} \leq & c \omega_{3}\left(F, \rho_{n}\left(x_{m}\right)\right)\left(\frac{1+x}{1+x_{m}}\right)^{2} \\
& +c \sum_{s=m+1}^{l} \omega_{3}\left(F, \rho_{n}\left(x_{s}\right)\right)\left[\left(\frac{1+x}{1+x_{s}}\right)^{2}-\left(\frac{1+x}{1+x_{s-1}}\right)^{2}\right] \\
= & I_{1}+I_{2}
\end{aligned}
$$

Now, for $m \leq s \leq l$, it follows that

$$
\begin{equation*}
\frac{\rho_{n}^{3}\left(x_{s}\right)}{\rho_{n}^{3}(x)}\left(\frac{1+x}{1+x_{s}}\right)^{3 / 2} \leq 64 \tag{4.24}
\end{equation*}
$$

where we recall that $x<x_{l-1}$.
Observe that

$$
\frac{1}{\left(1+x_{s}\right)^{2}}-\frac{1}{\left(1+x_{s-1}\right)^{2}} \leq c \frac{\left|I_{s}\right|}{\left(1+x_{s}\right)^{3}},
$$

so that by (4.24),

$$
\begin{align*}
I_{2} & \leq c \frac{\omega_{3}\left(F, \rho_{n}(x)\right)}{\rho_{n}^{3}(x)}(1+x)^{2} \sum_{s=m+1}^{l} \rho_{n}^{3}\left(x_{s}\right) \frac{\left|I_{s}\right|}{\left(1+x_{s}\right)^{3}} \\
& \leq c \omega_{3}\left(F, \rho_{n}(x)\right) \sum_{s=m+1}^{l} \frac{\left|I_{s}\right|}{\left(1+x_{s}\right)^{3 / 2}} \\
& \leq c \omega_{3}\left(F, \rho_{n}(x)\right)(1+x)^{1 / 2} \int_{x_{l}}^{x_{m}}(1+t)^{-3 / 2} d t \\
& \leq c \omega_{3}\left(F, \rho_{n}(x)\right)\left(\frac{1+x}{1+x_{l}}\right)^{1 / 2} . \tag{4.25}
\end{align*}
$$

Also,

$$
\begin{equation*}
I_{1} \leq c \frac{\rho_{n}^{3}\left(x_{m}\right)}{\rho_{n}^{3}(x)} \omega_{3}\left(F, \rho_{n}(x)\right)\left(\frac{1+x}{1+x_{m}}\right)^{2} \leq c \omega_{3}\left(F, \rho_{n}(x)\right) \tag{4.26}
\end{equation*}
$$

Combining (4.25) and (4.26), the proof is complete.
Remark 3. Lemma 4 is stated for the interval $[-1,0]$, but we need it also for the interval $[0,1]$. However, unlike Lemma 3 which was translated, practically verbatim, to $[0,1]$, a similar translation of Lemma 4 to $[0,1]$ is not helpful for the estimates on the approximation by the splines with nodes at the Chebyshev knots, due to the non symmetry of the truncated powers. Rather we will have to modify it. One should note that it is also possible to apply the same modification in order to translate Lemma 3 to the interval [ 0,1 ]. (See details in the last part of the proof of Lemma 7.) Nevertheless, we need the translation of Lemma 4 to [0, 1] for the estimates on the polynomial approximation, but we defer the statement for further preparations (see Lemma 11).

## 5. Auxiliary lemmas

We begin with a lemma.
Lemma 5. Let $\theta \in\left(x_{j}, x_{j-1}\right), N+1 \leq j \leq n-N$. For any $\gamma,|\gamma|<\frac{1}{3}\left|I_{j}\right|$, there are nonnegative numbers $\eta_{j}, \mu_{j}, v_{j}$ such that

$$
\begin{align*}
& \eta_{j}\left(x-x_{j+N}\right)^{2}+\mu_{j}\left(x-x_{j+1}\right)^{2}+v_{j}\left(x-x_{j-2}\right)^{2} \\
& \quad=(x-\theta)^{2}+h_{j}^{2}+\gamma\left(x-x_{j-2}\right), \quad x \in \mathbb{R}, \tag{5.1}
\end{align*}
$$

holds with $N \geq 1900$ and $h_{j}=7\left|I_{j}\right|$.

Proof. Comparing the coefficients of the various powers of $x$ on both sides of the equation, we observe that (5.1) is equivalent to the system of three linear equations

$$
\left\{\begin{array}{l}
\eta_{j}+\mu_{j}+v_{j}=1 \\
\eta_{j} x_{j+N}+\mu_{j} x_{j+1}+v_{j} x_{j-2}=\theta-\frac{\gamma}{2} \\
\eta_{j} x_{j+N}^{2}+\mu_{j} x_{j+1}^{2}+v_{j} x_{j-2}^{2}=\theta^{2}+h_{j}^{2}-\gamma x_{j-2}
\end{array}\right.
$$

The solution to the latter is given by

$$
\eta_{j}=\frac{\Delta_{\eta, j}}{\Delta_{j}}, \quad \mu_{j}=\frac{\Delta_{\mu, j}}{\Delta_{j}}, \quad v_{j}=\frac{\Delta_{v, j}}{\Delta_{j}}
$$

where by straightforward computations we have,

$$
\begin{aligned}
\Delta:= & \left(x_{j-2}-x_{j+1}\right)\left(x_{j-2}-x_{j+N}\right)\left(x_{j+1}-x_{j+N}\right)>0 \\
\Delta_{\eta, j}:= & \left(x_{j-2}-x_{j+1}\right)\left(\left(\theta-x_{j+1}\right)^{2}+h_{j}^{2}-\left(x_{j-2}-x_{j+1}\right)\left(\theta+\frac{\gamma}{2}-x_{j+1}\right)\right), \\
\Delta_{\mu, j}:= & \left(x_{j-2}-x_{j+N}\right)\left(\left(x_{j-2}-x_{j+N}\right)\left(\frac{\gamma}{2}+x_{j-2}-\theta\right)-\left(\theta-x_{j-2}\right)^{2}-h_{j}^{2}\right), \\
\Delta_{\nu, j}:= & \left(x_{j+1}-x_{j+N}\right)\left(\left(\theta-x_{j+1}\right)^{2}+h_{j}^{2}-\gamma\left(x_{j-2}-x_{j+1}\right)\right. \\
& \left.\quad+\left(x_{j+1}-x_{j+N}\right)\left(\theta-\frac{\gamma}{2}-x_{j+1}\right)\right) .
\end{aligned}
$$

Now,

$$
x_{j-2}-x_{j+1} \leq 7\left|I_{j}\right|,
$$

and

$$
x_{j+1}+\frac{\left|I_{j}\right|}{2} \leq \theta \pm \frac{\gamma}{2} \leq x_{j-2}-\frac{\left|I_{j}\right|}{2} .
$$

Hence, we obtain

$$
\begin{aligned}
h_{j}^{2}-\left(x_{j-2}-x_{j+1}\right)\left(\theta+\frac{\gamma}{2}-x_{j+1}\right) & \geq\left(7\left|I_{j}\right|\right)^{2}-\left(x_{j-2}-x_{j+1}\right)^{2} \\
& \geq\left(7\left|I_{j}\right|\right)^{2}-\left(7\left|I_{j}\right|\right)^{2}=0
\end{aligned}
$$

and as all other terms are nonnegative, we conclude that $\Delta_{\eta, j}>0$.
Even simpler is the inequality

$$
h_{j}^{2}-\gamma\left(x_{j-2}-x_{j+1}\right)>49\left|I_{j}\right|^{2}-\frac{1}{3}\left|I_{j}\right| \cdot 7\left|I_{j}\right|>0,
$$

so that, with all other terms being nonnegative, we conclude that $\Delta_{\nu, j}>0$.
Finally by virtue of (4.3) and (4.4), we obtain

$$
\left(x_{j+1}-x_{j+N}\right)\left(\frac{\gamma}{2}+x_{j-2}-\theta\right)>\frac{N-1}{\pi}\left|I_{j+1}\right| \frac{\left|I_{j}\right|}{2} \geq \frac{N-1}{6 \pi}\left|I_{j}\right|^{2} .
$$

Hence,

$$
\begin{aligned}
& \left(x_{j+1}-x_{j+N}\right)\left(\frac{\gamma}{2}+x_{j-2}-\theta\right)-\left(\theta-x_{j+1}\right)^{2}-h_{j}^{2} \\
& \quad>\frac{N-1}{6 \pi}\left|I_{j}\right|^{2}-49\left|I_{j}\right|^{2}-49\left|I_{j}\right|^{2}=\left(\frac{N-1}{6 \pi}-98\right)\left|I_{j}\right|^{2}>0
\end{aligned}
$$

since we recall that $N \geq 1900$. Thus, $\Delta_{\mu, j}>0$, and the proof is complete.

We also need the following lemma.
Lemma 6. For any $\theta \in\left(x_{j}, x_{j-1}\right), 1 \leq j \leq n-1$, there exists a piecewise quadratic spline $S_{\theta} \in \Delta^{3}$ with the Chebyshev knots, such that

$$
\begin{align*}
& S_{\theta}(x)=(x-\theta)^{2}, \quad x \in\left(x_{j-1}, 1\right]  \tag{5.2}\\
& \left|S_{\theta}(x)\right| \leq c\left(\frac{1+x}{1+x_{j}}\right)^{2}\left|I_{j}\right|^{2}, \quad x \in\left[-1, x_{j}\right)  \tag{5.3}\\
& \left|S_{\theta}(x)-(x-\theta)_{+}^{2}\right| \leq c\left|I_{j}\right|^{2}, \quad x \in\left[x_{j}, x_{j-1}\right] . \tag{5.4}
\end{align*}
$$

Proof. For $j=1$ we take $S_{\theta}(x):=\left(x-x_{1}\right)_{+}^{2}$ and observe that we have a stronger inequality (5.3), namely, $S_{\theta}(x)=0, x \in\left[-1, x_{1}\right)$.

Otherwise, $1<j<n$, so take

$$
S_{\theta}(x):=-\eta(1+x)^{2}+\mu\left(x-x_{j}\right)_{+}^{2}+v\left(x-x_{j-1}\right)_{+}^{2}, \quad x \in[-1,1],
$$

where

$$
\begin{aligned}
\eta & :=\frac{\left(x_{j-1}-\theta\right)\left(\theta-x_{j}\right)}{\left(x_{j-1}+1\right)\left(x_{j}+1\right)}, \\
\mu & :=\frac{\left(x_{j-1}-\theta\right)(\theta+1)}{\left(x_{j}+1\right)\left(x_{j-1}-x_{j}\right)}, \\
v & :=\frac{\left(\theta-x_{j}\right)(\theta+1)}{\left(x_{j-1}+1\right)\left(x_{j-1}-x_{j}\right)} .
\end{aligned}
$$

By definition, $\mu, v>0$, so that $S_{\theta} \in \Delta^{3}$. Also, straightforward computations yield (5.2). Thus, it is left to show (5.3) and (5.4). To this end, first let $x \in\left[-1, x_{j}\right]$. Then

$$
\begin{aligned}
\left|S_{\theta}(x)\right| & =\eta(1+x)^{2}=\frac{\left(x_{j-1}-\theta\right)\left(\theta-x_{j}\right)}{\left(x_{j-1}+1\right)\left(x_{j}+1\right)}(1+x)^{2} \\
& \leq\left(\frac{1+x}{1+x_{j}}\right)^{2}\left(x_{j-1}-\theta\right)\left(\theta-x_{j}\right) \\
& \leq \frac{1}{4}\left(\frac{1+x}{1+x_{j}}\right)^{2}\left|I_{j}\right|^{2},
\end{aligned}
$$

which proves (5.3). Finally, for $x \in\left(x_{j}, x_{j-1}\right]$, we have

$$
\begin{aligned}
\left|S_{\theta}(x)\right| & =\eta(1+x)^{2}+\mu\left(x-x_{j}\right)^{2} \\
& \leq \frac{1}{4}\left(\frac{1+x}{1+x_{j}}\right)^{2}\left|I_{j}\right|^{2}+\frac{\theta+1}{x_{j}+1}\left|I_{j}\right|^{2} \\
& \leq c\left|I_{j}\right|^{2},
\end{aligned}
$$

where for the last inequality we applied (4.4) to conclude that

$$
\begin{aligned}
\max \left\{\frac{1+x}{1+x_{j}}, \frac{1+\theta}{1+x_{j}}\right\} & \leq \frac{1+x_{j-1}}{1+x_{j}} \\
& =1+\frac{x_{j-1}-x_{j}}{x_{j}-x_{n}} \leq 1+3 \pi
\end{aligned}
$$

This combined with the fact that

$$
(x-\theta)_{+}^{2} \leq\left|I_{j}\right|^{2}, \quad x \in\left(x_{j}, x_{j-1}\right]
$$

completes the proof of (5.4) and, thus, of the lemma.
We apply the above lemmas to remove the unwanted $\theta_{j}$ 's.
Lemma 7. Suppose $\theta_{j} \in\left(x_{j}, x_{j-1}\right), j=N+1, \ldots, n-N-1$, and

$$
\sigma(x)=\sum_{j=N+1}^{n-N-1} q_{j}\left(x-\theta_{j}\right)_{+}^{2},
$$

and assume that the coefficients are such that for some $F \in C[-1,1]$,

$$
0 \leq q_{j}\left|I_{j}\right|^{2} \leq c \omega_{3}\left(F, \rho_{n}\left(x_{j}\right)\right), \quad j=N+1, \ldots, n-N-1
$$

Then there is a piecewise quadratic spline $\sigma_{1} \in \Delta^{3}$ with nodes at the Chebyshev knots, satisfying

$$
\left|\sigma(x)-\sigma_{1}(x)\right| \leq \tilde{c} \omega_{3}\left(F, \rho_{n}(x)\right), \quad x \in[-1,1]
$$

Proof. We first point out that by virtue of Lemma 5, for each $j, N+1 \leq j \leq n-N-1$,

$$
\begin{align*}
(x- & \left.\theta_{j}\right)_{+}^{2}-\left(\eta_{j}\left(x-x_{j+N}\right)_{+}^{2}+\mu_{j}\left(x-x_{j+1}\right)_{+}^{2}+v_{j}\left(x-x_{j-2}\right)_{+}^{2}\right) \\
& -h_{j}^{2}\left(x-x_{j-2}\right)_{+}^{0}-\gamma_{j}\left(x-x_{j-2}\right)_{+} \\
= & \begin{cases}0, & \text { if } x>x_{j-2}, \text { or } x \leq x_{j+N}, \\
R_{j}(x), & \text { for } x_{j+N}<x \leq x_{j-2},\end{cases} \tag{5.5}
\end{align*}
$$

where $\gamma_{j}$ is to be prescribed, and

$$
\begin{equation*}
\left|R_{j}(x)\right| \leq c\left|I_{j}\right|^{2}, \quad x_{j+N}<x \leq x_{j-2} \tag{5.6}
\end{equation*}
$$

We split the summation in $\sigma$ into two parts, the sum of the terms with $\lceil n / 2\rceil+2 \leq j \leq n-N-1$, and the rest (which is treated similarly, see the last part of the proof).

Consider the sum

$$
\sum_{j=\lceil n / 2\rceil+2}^{n-N-1} q_{j} h_{j}^{2}\left(x-x_{j-2}\right)_{+}^{0}=\sum_{j=\lceil n / 2\rceil}^{n-N-3} q_{j+2} h_{j+2}^{2}\left(x-x_{j}\right)_{+}^{0} .
$$

Our strategy is to apply Lemma 3. Let $D$ be taken so that

$$
\begin{equation*}
\frac{h_{j}^{2}}{D\left|I_{j-2}\right|}<\frac{1}{3}\left|I_{j}\right|, \quad j=\lceil n / 2\rceil, \ldots, n-N-3 \tag{5.7}
\end{equation*}
$$

We begin by setting $k_{1}=n-N-3$, and we let $s_{1}<k_{1}$ be so that $s_{1} \geq\lceil n / 2\rceil$, and the conditions of Lemma 3 are satisfied for $s=s_{1}, k=k_{1}$, with $\alpha_{j}:=h_{j+2}^{2} q_{j+2}$. Note that $\alpha_{j} \leq c \omega_{3}\left(F, \rho_{n}\left(x_{j}\right)\right),\lceil n / 2\rceil \leq j \leq n-N-3$, for some constant $c$. Clearly if $s_{1}=\lceil n / 2\rceil$, we are done with the construction. Otherwise, set $k_{2}:=s_{1}-1>\lceil n / 2\rceil$ and let $s_{2},\lceil n / 2\rceil \leq s_{2}<k_{2}$, be chosen similarly, with the conditions of Lemma 3 to be satisfied. We proceed like that and let
$\lceil n / 2\rceil \leq s_{m}<k_{m}$ be the last pair to be chosen in this manner. We apply Lemmas 3 and 5, for each pair $\left(s_{i}, k_{i}\right)$, obtaining a piecewise linear spline

$$
S(x)=\sum_{j=s_{m}}^{n-N-3} \frac{\beta_{j}}{\left|I_{j}\right|}\left(x-x_{j}\right)_{+}=\sum_{j=s_{m}+2}^{n-N-1} \frac{\beta_{j-2}}{\left|I_{j-2}\right|}\left(x-x_{j-2}\right)_{+} .
$$

Observe that we may choose in (5.5),

$$
\gamma_{j}=-\frac{\beta_{j-2}}{q_{j}\left|I_{j-2}\right|}
$$

since the only requirement in Lemma 5 is that $\left|\gamma_{j}\right|<\frac{1}{3}\left|I_{j}\right|$, that is guaranteed by (5.7). Hence,

$$
\sum_{j=s_{m}+2}^{n-N-1}\left(\frac{\beta_{j-2}}{\left|I_{j-2}\right|}\left(x-x_{j-2}\right)_{+}+q_{j} \gamma_{j}\left(x-x_{j-2}\right)_{+}\right)=0
$$

and in view of the above construction,

$$
\begin{align*}
& \left|\sum_{j=s_{m}+2}^{n-N-1} q_{j} h_{j}^{2}\left(x-x_{j-2}\right)_{+}^{0}+\sum_{j=s_{m}+2}^{n-N-1} q_{j} \gamma_{j}\left(x-x_{j-2}\right)_{+}\right| \\
& \quad=\left|\sum_{j=s_{m}+2}^{n-N-1} q_{j} h_{j}^{2}\left(x-x_{j-2}\right)_{+}^{0}-\sum_{j=s_{m}+2}^{n-N-1} \frac{\beta_{j-2}}{\left|I_{j-2}\right|}\left(x-x_{j-2}\right)_{+}\right| \\
& \quad \leq c \omega_{3}\left(F, \rho_{n}(x)\right), \quad x \in[-1,1] . \tag{5.8}
\end{align*}
$$

Also, given $x_{i} \leq x<x_{i-1}, N<i<n-N$, we get by (6.5) and (5.6),

$$
\begin{equation*}
\sum_{j=s_{m}+2}^{n-N-1} q_{j}\left|R_{j}(x)\right| \leq \sum_{j=i-N}^{i+1} q_{j}\left|R_{j}(x)\right| \leq c \sum_{j=i-N}^{i+1} \omega\left(F, \rho_{n}\left(x_{j}\right)\right) \leq c \omega_{3}\left(F, \rho_{n}(x)\right) \tag{5.9}
\end{equation*}
$$

where for the last inequality we have applied (4.1) and (4.2).
Thus, letting

$$
\begin{equation*}
S_{1}(x):=\sum_{j=s_{m}+2}^{n-N-1} q_{j}\left(\eta_{j}\left(x-x_{j+N}\right)_{+}^{2}+\mu_{j}\left(x-x_{j+1}\right)_{+}^{2}+v_{j}\left(x-x_{j-2}\right)_{+}^{2}\right) \tag{5.10}
\end{equation*}
$$

it follows by (5.8) and (5.9) that

$$
\begin{equation*}
\left|\sum_{j=s_{m}+2}^{n-N-1} q_{j}\left(x-\theta_{j}\right)_{+}^{2}-S_{1}(x)\right| \leq c \omega_{3}\left(F, \rho_{n}(x)\right), \quad x \in[-1,1] . \tag{5.11}
\end{equation*}
$$

If it so happens that $s_{m}=\lceil n / 2\rceil$, then we are done. Otherwise, our process stops, that is, we have an index $k$ (which may even be $k=k_{1}$ ), and we cannot find $s<k$ so that the conditions of Lemma 3 are satisfied. Namely, we have the inequalities

$$
\sum_{j=s}^{k+2} q_{j}\left|I_{j}\right|^{2} \leq C D \omega_{3}\left(F, \rho_{n}\left(x_{s}\right)\right), \quad s=\lceil n / 2\rceil+2, \ldots, k+2
$$

Then we go back to the original sum $\sum_{j=\lceil n / 2\rceil+2}^{k+2} q_{j}\left(x-\theta_{j}\right)_{+}^{2}$, and approximate it using Lemma 6.

To this end, note that by virtue of Lemma 6, for $x_{l} \leq x<x_{l-1},\lceil n / 2\rceil \leq l \leq k+3$, and for $-1 \leq x<x_{k+1}, l=k+2$,

$$
\begin{align*}
\sum_{j=\lceil n / 2\rceil+2}^{k+2} q_{j}\left|\left(x-\theta_{j}\right)_{+}^{2}-S_{\theta_{j}}(x)\right| & \leq \sum_{j=\lceil n / 2\rceil+2}^{l} q_{j}\left|I_{j}\right|^{2}\left(\frac{1+x}{1+x_{j}}\right)^{2} \\
& \leq C D \omega_{3}\left(F, \rho_{n}(x)\right) \tag{5.12}
\end{align*}
$$

where for the last inequality we have applied Lemma 4.
Denoting

$$
S_{2}(x):=\sum_{j=\lceil n / 2\rceil+2}^{k+2} q_{j} S_{\theta_{j}}(x)
$$

and setting

$$
S:=S_{1}+S_{2}
$$

we conclude that $S \in \Delta^{3}$, and it follows by (5.11) and (5.12) that,

$$
\begin{equation*}
\left|\sum_{j=\lceil n / 2\rceil+2}^{n-N-1} q_{j}\left(x-\theta_{j}\right)_{+}^{2}-S(x)\right| \leq C D \omega_{3}\left(F, \rho_{n}(x)\right), \quad x \in[-1,1] . \tag{5.13}
\end{equation*}
$$

As mentioned at the beginning of the proof, we construct a similar 3-monotone piecewise quadratic spline with nodes at the Chebyshev knots, approximating

$$
\sum_{j=N+1}^{\lceil n / 2\rceil+1} q_{j}\left(x-\theta_{j}\right)_{+}^{2} .
$$

First we apply the construction of Lemma 3; see Remark 2. However, again we may have an index $k \geq N+1$ such that

$$
\sum_{j=k+2}^{s} q_{j}\left|I_{j}\right|^{2} \leq C D \omega_{3}\left(F, \rho_{n}\left(x_{s}\right)\right), \quad s=k+2, \ldots,\lceil n / 2\rceil+1
$$

Thus, we need to apply an analogue of Lemma 4.
To this end, we observe that

$$
\begin{equation*}
(x-t)_{+}^{2}=(x-t)^{2}-(-x+t)_{+}^{2} \tag{5.14}
\end{equation*}
$$

Hence, substituting $y:=-x$ and $\tau_{j}:=-\theta_{j}$,

$$
\begin{aligned}
\sum_{j=k+2}^{\lceil n / 2\rceil+1} q_{j}\left(x-\theta_{j}\right)_{+}^{2} & =\sum_{j=k+2}^{\lceil n / 2\rceil+1} q_{j}\left(x-\theta_{j}\right)^{2}-\sum_{j=k+2}^{\lceil n / 2\rceil+1} q_{j}\left(-x+\theta_{j}\right)_{+}^{2} \\
& =: P(x)-\sum_{j=k+2}^{\lceil n / 2\rceil+1} q_{j}\left(y-\tau_{j}\right)_{+}^{2}
\end{aligned}
$$

Note that $P(x)$ is a quadratic polynomial. Denote $y_{j}:=-x_{j}$. Then $\tau_{j} \in\left(y_{j-1}, y_{j}\right) \subset[-1,0]$, except for $y_{\lceil n / 2\rceil+1}$ and, perhaps, $y_{\lceil n / 2\rceil}$ (the latter, only if $n$ is odd), but this requires no significant
modification in the proof of Lemma 4. Thus, by Lemmas 4 and 6, there exists a quadratic spline $\hat{S}(y) \in \Delta^{3}$ such that

$$
\left|\sum_{j=k+2}^{\lceil n / 2\rceil+1} q_{j}\left(y-\tau_{j}\right)_{+}^{2}-\hat{S}(y)\right| \leq C D \omega_{3}\left(F, \rho_{n}(y)\right), \quad y \in[-1,1]
$$

which in turn implies

$$
\left|\sum_{j=k+2}^{\lceil n / 2\rceil+1} q_{j}\left(x-\theta_{j}\right)_{+}^{2}-(P(x)-\hat{S}(-x))\right| \leq C D \omega_{3}\left(F, \rho_{n}(x)\right), \quad x \in[-1,1]
$$

Finally, we observe that $P(x)-\hat{S}(-x) \in \Delta^{3}$. This completes the proof.

## 6. Quadratic spline with nodes at the Chebyshev knots

We are ready to prove Theorem 2.
Proof of Theorem 2. Given $F \in \Delta^{3}$, the function $f:=F^{\prime} \in C(-1,1)$, is convex. Let $s(x)$ denote the piecewise linear interpolant of $f$ on the Chebyshev knots $x_{n-1}<\cdots<x_{1}$. Then, it readily follows that $s$ is convex and the requirements of Theorem 1 are satisfied in $\left[x_{n-1}, x_{1}\right]$. It was proved in [10, Lemma 3] that

$$
\int_{x_{i}}^{x_{i-1}}|f(t)-s(t)| d t \leq c \omega_{3}\left(F,\left(x_{i-2}-x_{i+1}\right) / 3 ;\left[x_{i+1}, x_{i-2}\right]\right), \quad 2 \leq i \leq n-1
$$

Hence, by Theorem 1 (2.1), we obtain a piecewise quadratic $S \in \Delta^{3}\left[x_{n-1}, x_{1}\right]$ satisfying

$$
\begin{equation*}
|F(x)-S(x)| \leq c \omega_{3}\left(F, \rho_{n}(x)\right), \quad x \in\left[x_{n-1}, x_{1}\right] \tag{6.1}
\end{equation*}
$$

where we used (4.1)-(4.3).
However, note that $S$ may have nodes not only at the Chebyshev knots but, perhaps, also at some $\theta_{j} \in\left(x_{j}, x_{j-1}\right), 2 \leq j \leq n-1$.

We extend the definition of $S$ to the end intervals by

$$
S_{\left[x_{1}, 1\right]}:=F^{\prime \prime}\left(x_{1}-\right)\left(\cdot-x_{1}\right)^{2}+F^{\prime}\left(x_{1}\right)\left(\cdot-x_{1}\right)+F\left(x_{1}\right),
$$

and

$$
S_{\left[-1, x_{n-1}\right]}:=F^{\prime \prime}\left(x_{n-1}+\right)\left(\cdot-x_{n-1}\right)^{2}+F^{\prime}\left(x_{n-1}\right)\left(\cdot-x_{n-1}\right)+F\left(x_{n-1}\right)
$$

Again, by [10, Lemma 3]

$$
\begin{aligned}
& \int_{x_{1}}^{1}\left|f(t)-S^{\prime}(t)\right| d t \leq c \omega_{3}\left(F,\left(1-x_{3}\right) / 3 ;\left[x_{3}, 1\right]\right) \\
& \int_{-1}^{x_{n-1}}\left|f(t)-S^{\prime}(t)\right| d t \leq c \omega_{3}\left(F,\left(x_{n-3}+1\right) / 3 ;\left[-1, x_{n-3}\right]\right)
\end{aligned}
$$

so that, combined with (6.1), we have

$$
\begin{equation*}
|F(x)-S(x)| \leq c \omega_{3}\left(F, \rho_{n}(x)\right), \quad x \in[-1,1] . \tag{6.2}
\end{equation*}
$$

Clearly, we may write

$$
S(x)=: P^{*}(x)+\sum_{i=1}^{n-1} \alpha_{i}\left(x-x_{i}\right)_{+}^{2}+\sum_{i=2}^{n-1} q_{i}\left(x-\theta_{i}\right)_{+}^{2}, \quad x \in[-1,1]
$$

where $P^{*}$ is a polynomial of degree $\leq 2$, and all $\alpha_{i} \geq 0,1 \leq i \leq n-1$ and $q_{i} \geq 0,2 \leq i$ $\leq n-1$.

We proceed to remove the terms involving $\theta_{j}, N+1 \leq j \leq n-N-1$. This we do by virtue of Lemma 7, by showing that $q_{j}\left|I_{j}\right|^{2} \leq c \omega_{3}\left(F, \rho_{n}\left(x_{j}\right)\right), N+1 \leq j \leq n-N-1$. To this end, observe that by (1.3),

$$
B_{h}(x):=\Delta_{h}^{3}\left((\cdot)_{+}^{2}, x\right) \geq 0, \quad x \in[-2,2],
$$

and

$$
\Delta_{h}^{3}\left((\cdot)_{+}^{2}, x\right) \geq h^{2}, \quad \text { for }-2 h \leq x \leq-h
$$

For $h=\frac{1}{7}\left|I_{j}\right|, N+2 \leq j \leq n-N-1$, let $x-\theta_{j} \in[-2 h,-h]$. Then it follows that

$$
\Delta_{h}^{3}(S, x)=\sum_{i=1}^{n-1} \alpha_{i} B_{h}\left(x-x_{i}\right)+\sum_{i=2}^{n-1} q_{i} B_{h}\left(x-\theta_{i}\right) \geq q_{j} B_{h}\left(x-\theta_{j}\right) \geq \frac{q_{j}}{49}\left|I_{j}\right|^{2} .
$$

On the other hand, by (1.2), for all $x$ such that $x-\theta_{j} \in[-2 h,-h]$,

$$
\Delta_{h}^{3}(S, x) \leq \omega_{3}\left(S,\left(x_{j-2}-x_{j+1}\right) ;\left[x_{j+1}, x_{j-2}\right]\right) \leq c \omega_{3}\left(F, \rho_{n}\left(x_{j}\right)\right)
$$

where we applied (6.2), and (4.1) and (4.3).
Hence, we conclude that

$$
q_{j}\left|I_{j}\right|^{2} \leq c \omega_{3}\left(F, \rho_{n}\left(x_{j}\right)\right), \quad j=N+1, \ldots, n-N-1 .
$$

Therefore, by virtue of Lemma 7, we have a 3-monotone piecewise quadratic $\bar{S}$ with nodes at the Chebyshev knots and perhaps additional nodes at $\theta_{i}, 1 \leq i \leq N$ and $n-N \leq i \leq n$, such that

$$
|S(x)-\bar{S}(x)| \leq c \omega_{3}\left(F, \rho_{n}(x)\right)
$$

which in turn by (6.2) implies

$$
\begin{equation*}
|F(x)-\bar{S}(x)| \leq c \omega_{3}\left(F, \rho_{n}(x)\right), \quad x \in[-1,1] \tag{6.3}
\end{equation*}
$$

For later purposes, let $\bar{S}$ be represented by

$$
\begin{align*}
\bar{S}(x)= & P^{*}(x)+\sum_{i=n-N}^{n-1} q_{i}\left(x-\theta_{i}\right)_{+}^{2}+\sum_{i=1}^{n-1} \lambda_{i}\left(x-x_{i}\right)_{+}^{2} \\
& +\sum_{i=2}^{N} q_{i}\left(x-\theta_{i}\right)_{+}^{2}, \quad x \in[-1,1] \tag{6.4}
\end{align*}
$$

where, evidently, $\lambda_{i} \geq 0, i=N, \ldots, n-N-1$, and by the same proof as above (estimating $q_{i}$ ), we conclude that

$$
\begin{equation*}
\lambda_{i}\left|I_{i}\right|^{2} \leq c \omega_{3}\left(F, \rho_{n}\left(x_{i}\right)\right), \quad i=N, \ldots, n-N-1 \tag{6.5}
\end{equation*}
$$

We replace $\bar{S}$ on the intervals $\left[x_{N+1}, 1\right]$ and $\left[-1, x_{n-N-1}\right]$, by the parabolas $S_{1}(x):=$ $\frac{1}{2} \bar{S}^{\prime \prime}\left(x_{N+1}+\right)\left(x-x_{N+1}\right)^{2}+\bar{S}^{\prime}\left(x_{N+1}\right)\left(x-x_{N+1}\right)+\bar{S}\left(x_{N+1}\right)$ and

$$
S_{n}(x):=\frac{1}{2} \bar{S}^{\prime \prime}\left(x_{n-N-1}-\right)\left(x-x_{n-N-1}\right)^{2}+\bar{S}^{\prime}\left(x_{n-N-1}\right)\left(x-x_{n-N-1}\right)+\bar{S}\left(x_{n-N-1}\right)
$$

respectively. By virtue of [10, Lemma 3] and (6.3), we obtain

$$
\left|\bar{S}(x)-S_{1}(x)\right| \leq c \omega_{3}\left(F, \rho_{n}(x)\right), \quad x \in \cup_{i=1}^{N+1} I_{i}
$$

and

$$
\left|\bar{S}(x)-S_{n}(x)\right| \leq c \omega_{3}\left(F, \rho_{n}(x)\right), \quad x \in \cup_{i=n-N}^{n} I_{i}
$$

where, again, we have applied (4.1) and (4.3).
Denote

$$
\hat{S}(x):= \begin{cases}\bar{S}(x), & x_{n-N-1}<x<x_{N+1} \\ S_{1}(x), & x \in \cup_{i=1}^{N+1} I_{i}, \\ S_{n}(x), & x \in \cup_{i=n-N}^{n} I_{i} .\end{cases}
$$

Then, $\hat{S} \in \Delta^{3}$, is piecewise quadratic with nodes only at the Chebyshev knots. Finally, it follows by (6.3) that

$$
\begin{equation*}
|F(x)-\hat{S}(x)| \leq c \omega_{3}\left(F, \rho_{n}(x)\right), \quad x \in[-1,1], \tag{6.6}
\end{equation*}
$$

where we applied (4.1). We have proved (6.6) for $n>2 N+1$. By virtue of Whitney's theorem the quadratic polynomial that interpolates $F$ at $-1,0,1$, yields an approximation to $F$ which is bounded by $\omega_{3}(F, 1)$ (and any quadratic polynomial is automatically in $\Delta^{3}$ ). Hence, since $\rho_{n}(x) \geq \frac{1}{n^{2}}$, we may extend (6.6) down to $n \geq 1$. This completes our proof.
For constructing the polynomial approximant in the next section, we need an explicit representation of $\hat{S}$ (surprisingly, it looks asymmetric, but this is due to the asymmetry of the truncated powers $\left.(\cdot-t)_{+}^{2}\right)$. This is the purpose of the following lemma.

Lemma 8. The following representation of $\hat{S}$ is valid.

$$
\begin{aligned}
\hat{S}(x)= & P^{*}(x)+\sum_{i=n-N}^{n-1} q_{i}\left(x-\theta_{i}\right)^{2}+\sum_{i=n-N}^{n-1} \lambda_{i}\left(x-x_{i}\right)^{2} \\
& +\sum_{i=N+1}^{n-N-1} \lambda_{i}\left(x-x_{i}\right)_{+}^{2}=: \tilde{S}(x), \quad x \in[-1,1] .
\end{aligned}
$$

Proof. We only have to compare the values of $\hat{S}$ and $\tilde{S}$ near the end points, for both are equal to $\bar{S}$ in $\left[x_{n-N-1}, x_{N+1}\right]$. Observe that both $\tilde{S}(x)$ and $S_{1}(x)$ are quadratic polynomials in $\left[x_{N+1}, 1\right]$, that agree up to the second derivative at $x_{N+1}$, hence identical. Similarly, observe that both $\tilde{S}(x)$ and $S_{n}(x)$ are quadratic polynomials in $\left[-1, x_{n-N-1}\right]$, that agree up to the second derivative at $x_{n-N-1}$, hence identical. This completes the proof.

## 7. Pointwise polynomial approximation

We are ready to prove Theorem 3. We begin with some auxiliary lemmas.
Lemma 9. For every $n$ and $1 \leq j \leq n-1$, there exist a polynomial $P_{j} \in \mathcal{P}_{n+1} \cap \Delta^{3}$ and a number $h_{j}$ such that $0 \leq h_{j} \leq c \rho_{n}^{2}\left(x_{j}\right)$, and we have the following estimates.

$$
\begin{equation*}
\left|\left(x-x_{j}\right)_{+}^{2}+h_{j}\left(x-x_{j}\right)_{+}^{0}-P_{j}(x)\right| \leq c \rho_{n}^{2}(x)\left(\frac{\left|I_{j}\right|}{\rho_{n}(x)+\left|x-x_{j}\right|}\right)^{3} \tag{7.1}
\end{equation*}
$$

and

$$
\begin{equation*}
\left|\left(x-x_{j}\right)_{+}^{2}+h_{j}\left(x-x_{j}\right)_{+}^{0}-P_{j}(x)\right| \leq \frac{c \rho_{n}^{8.5}(x)}{\left(\rho_{n}(x)+\left|x-x_{j}\right|\right)^{6.5}} \tag{7.2}
\end{equation*}
$$

Proof. By the proof of [2, Lemma 1] there exist $P_{j} \in \mathcal{P}_{n+1} \cap \Delta^{3}$ and $\left|h_{j}\right| \leq c \rho_{n}^{2}\left(x_{j}\right)$, such that

$$
\begin{equation*}
\left|\left(x-x_{j}\right)_{+}^{2}+h_{j}\left(x-x_{j}\right)_{+}^{0}-P_{j}(x)\right| \leq \frac{c \rho_{n}^{17}\left(x_{j}\right)}{\left(\rho_{n}\left(x_{j}\right)+\left|x-x_{j}\right|\right)^{15}}, \tag{7.3}
\end{equation*}
$$

and in turn (7.1) holds (see there).
Now, by virtue of (4.5),

$$
\begin{aligned}
\left(\rho_{n}(x)+\left|x-x_{j}\right|\right)^{2} & \leq 2\left(\rho_{n}^{2}(x)+\left|x-x_{j}\right|^{2}\right) \\
& \leq c\left(\rho_{n}\left(x_{j}\right)\left(\rho_{n}\left(x_{j}\right)+\left|x-x_{j}\right|\right)+\left|x-x_{j}\right|^{2}\right) \\
& \leq c\left(\rho_{n}\left(x_{j}\right)+\left|x-x_{j}\right|\right)^{2}
\end{aligned}
$$

which, in turn, combined with (4.6), yields

$$
\begin{aligned}
\frac{\rho_{n}^{17}\left(x_{j}\right)}{\left(\rho_{n}\left(x_{j}\right)+\left|x-x_{j}\right|\right)^{15}} & \leq \frac{c\left(\rho_{n}(x)\left(\rho_{n}(x)+\left|x-x_{j}\right|\right)\right)^{8.5}}{\left(\rho_{n}(x)+\left|x-x_{j}\right|\right)^{15}} \\
& \leq \frac{c \rho_{n}^{8.5}(x)}{\left(\rho_{n}(x)+\left|x-x_{j}\right|\right)^{6.5}}
\end{aligned}
$$

Substituting in (7.3) we obtain (7.2). We are left with having to prove that $h_{j} \geq 0$. To this end, we note that [2, Lemma 1] was proved using [6] construction of convex polynomials $\sigma_{j} \in \mathcal{P}_{n}$ on $[-1,1]$ such that

$$
\sigma_{j}(-1)=0, \quad \sigma_{j}(1)=1-x_{j}, \quad 0 \leq \sigma_{j}^{\prime}(x) \leq 1, x \in[-1,1]
$$

(See [6, pp. 164-165] for the definition of $\sigma_{j}$ and the above properties.)
Hence,

$$
\sigma_{j}(t)-\left(t-x_{j}\right)_{+}=\int_{-1}^{t} \sigma_{j}^{\prime}(y) d y \geq 0, \quad t \in\left[-1, x_{j}\right]
$$

and

$$
\sigma_{j}(t)-\left(t-x_{j}\right)_{+}=\int_{t}^{1}\left(1-\sigma_{j}^{\prime}(y)\right) d y \geq 0, \quad t \in\left[x_{j}, 1\right]
$$

Recall that the polynomials $P_{j}$ and the constants $h_{j}$ were defined by

$$
P_{j}(x)=2 \int_{-1}^{x} \sigma_{j}(t) d t \quad \text { and } \quad h_{j}=2 \int_{-1}^{1}\left(\sigma_{j}(t)-\left(t-x_{j}\right)_{+}\right) d t
$$

Thus, we immediately conclude that $h_{j} \geq 0$. This completes the proof.
Remark 4. Note that Kopotun's [6] construction of $\sigma_{j}$ yields polynomials of degree $c n$. Thus, in order to have the polynomials of degree $n$, we take the Kopotun construction for $n_{1}:=[n / c]$. However, in order to avoid unnecessary cumbersome notation, we continue to call it $n$.

Remark 5. Since we will have to use often the inequalities (7.1) and (7.2), we introduce a single notation for both right hand sides. Thus, denote

$$
\begin{equation*}
A_{n, j}(x):=\min \left\{\rho_{n}^{2}(x)\left(\frac{\left|I_{j}\right|}{\rho_{n}(x)+\left|x-x_{j}\right|}\right)^{3}, \frac{\rho_{n}^{8.5}(x)}{\left(\rho_{n}(x)+\left|x-x_{j}\right|\right)^{6.5}}\right\} . \tag{7.4}
\end{equation*}
$$

Lemma 10. There is an $N$ such that for every $n>2 N+1$ and $N \leq j \leq n / 2$, there exists a polynomial $Q_{j} \in \mathcal{P}_{n+1} \cap \Delta^{3}$ such that the following inequalities hold.

$$
\begin{equation*}
\left|\left(x-x_{j}\right)_{+}^{2}-Q_{j}(x)\right| \leq c A_{n, j}(x), \quad x \in\left[-1, x_{j}\right] \tag{7.5}
\end{equation*}
$$

and

$$
\begin{equation*}
\left|\left(x-x_{j}\right)_{+}^{2}-Q_{j}(x)\right| \leq c\left(\frac{1-x}{1-x_{j}}\right)^{2}\left|I_{j}\right|^{2}+c A_{n, j}(x), \quad x \in\left(x_{j}, 1\right] \tag{7.6}
\end{equation*}
$$

Proof. Fix $N>0$ large enough, to be prescribed, and let $b:=\kappa n^{-2}:=\max _{N \leq j \leq n / 2} \frac{16 h_{j}}{1-x_{j}}<1$, where $\kappa=\kappa(n)=O(1)$. Set

$$
Q_{j}(x):=\gamma_{j} P_{j}\left(\frac{x-\xi_{j}}{1+b}\right), \quad N \leq j \leq n / 2
$$

where the polynomials $P_{j}$ are given in Lemma 9 , and $\gamma_{j}$ and $\xi_{j}$ are determined by the conditions $T_{j}(1)=T_{j}^{\prime}(1)=0$, where

$$
T_{j}(x):=\gamma_{j}\left(\frac{x-\xi_{j}}{1+b}-x_{j}\right)^{2}+\gamma_{j} h_{j}-\left(x-x_{j}\right)^{2}
$$

The conditions $T_{j}(1)=T_{j}^{\prime}(1)=0$ are equivalent to the following system of two equations:

$$
\left\{\begin{array}{l}
\frac{\gamma_{j}}{(1+b)^{2}}\left(1-x_{j}-\xi_{j}-b x_{j}\right)^{2}+\gamma_{j} h_{j}=\left(1-x_{j}\right)^{2} \\
\frac{\gamma_{j}}{(1+b)^{2}}\left(1-x_{j}-\xi_{j}-b x_{j}\right)=1-x_{j}
\end{array}\right.
$$

Eliminating $\gamma_{j}$, we obtain a quadratic equation for $\xi_{j}$,

$$
\xi_{j}^{2}+\left(2 b x_{j}+x_{j}-1\right) \xi_{j}+(1+b)^{2} h_{j}+b x_{j}\left(b x_{j}+x_{j}-1\right)=0
$$

For $N>0$ sufficiently large, the discriminant of the above equation, $\left(1-x_{j}\right)^{2}-4(1+b)^{2} h_{j}$, is positive, and we take $\xi_{j}$ to be the solution

$$
\xi_{j}:=-b x_{j}+\frac{\left(1-x_{j}\right)-\sqrt{\left(1-x_{j}\right)^{2}-4(1+b)^{2} h_{j}}}{2}
$$

Then straightforward computations yield

$$
\gamma_{j}=\frac{2(1+b)^{2}}{1+\sqrt{1-\frac{4(1+b)^{2} h_{j}}{\left(1-x_{j}\right)^{2}}}}
$$

and since $h_{j} \geq 0$, this implies that $(1+b)^{2} \leq \gamma_{j} \leq 2(1+b)^{2} \leq 8$, and

$$
\begin{equation*}
0 \leq \frac{\gamma_{j}}{(1+b)^{2}}-1 \leq \frac{4(1+b)^{2} h_{j}}{\left(1-x_{j}\right)^{2}} \tag{7.7}
\end{equation*}
$$

Also, since $h_{j} \geq 0$, we have by the definition of $b$,

$$
0 \leq \xi_{j}+b x_{j}=\frac{4(1+b)^{2} h_{j}}{\left(1-x_{j}\right)+\sqrt{\left(1-x_{j}\right)^{2}-4(1+b)^{2} h_{j}}} \leq \frac{16 h_{j}}{1-x_{j}} \leq b
$$

Hence, $\left|\xi_{j}\right|<b$.
Set $x^{\prime}:=\left(x-\xi_{j}\right) /(1+b)$. Then

$$
\begin{equation*}
-1 \leq x^{\prime} \leq 1, \quad \text { and } \quad\left|x-x^{\prime}\right| \leq 2 \kappa n^{-2}, \quad x \in[-1,1], \tag{7.8}
\end{equation*}
$$

so that $c_{1} \rho_{n}(x) \leq \rho_{n}\left(x^{\prime}\right) \leq c_{2} \rho_{n}(x)$, and

$$
\begin{equation*}
\rho_{n}(x)+\left|x-x_{j}\right| \leq c \rho_{n}\left(x^{\prime}\right)+\left|x^{\prime}-x_{j}\right|+c n^{-2} \leq c\left(\rho_{n}\left(x^{\prime}\right)+\left|x^{\prime}-x_{j}\right|\right) \tag{7.9}
\end{equation*}
$$

Fix $j, N \leq j \leq n / 2$. If $x \in[-1,1]$ is such that $x^{\prime} \in\left[-1, x_{j}\right]$, then by Lemma 9 and (7.9), we obtain

$$
\begin{equation*}
\left|P_{j}\left(\frac{x-\xi_{j}}{1+b}\right)\right| \leq c A_{n, j}(x) . \tag{7.10}
\end{equation*}
$$

If $x^{\prime} \in\left(x_{j}, 1\right]$ and $x \in\left[-1, x_{j}\right]$, then $0 \leq x_{j}-x^{\prime} \leq x-x^{\prime} \leq 2 \kappa n^{-2} \leq c\left|I_{j}\right|, 0 \leq h_{j} \leq c\left|I_{j}\right|^{2}$, and $A_{n, j}(x) \geq c\left|I_{j}\right|^{2}$. Hence, by Lemma 9 and (7.9),

$$
\begin{aligned}
\left|P_{j}\left(\frac{x-\xi_{j}}{1+b}\right)-\left(\frac{x-\xi_{j}}{1+b}-x_{j}\right)^{2}-h_{j}\right| \leq & \left|P_{j}\left(\frac{x-\xi_{j}}{1+b}\right)\right| \\
& +\left(x^{\prime}-x_{j}\right)^{2}+h_{j} \leq c A_{n, j}(x)
\end{aligned}
$$

Hence, together with (7.10), we obtain (7.5).
In order to prove (7.6), fix $x \in\left(x_{j}, 1\right]$. If $x^{\prime} \in\left[-1, x_{j}\right]$, then $\left(x-x_{j}\right)^{2} \leq c\left|I_{j}\right|^{2} \leq c A_{n, j}(x)$. Thus, by (7.10),

$$
\left|\left(x-x_{j}\right)^{2}+Q_{j}(x)\right| \leq\left(x-x_{j}\right)^{2}+\left|Q_{j}(x)\right| \leq c A_{n, j}(x)
$$

and (7.6) is proved.
Otherwise, $x^{\prime} \in\left(x_{j}, 1\right]$. Then by Lemma 9 and (7.9), we obtain

$$
\left|P_{j}\left(\frac{x-\xi_{j}}{1+b}\right)-\left(\frac{x-\xi_{j}}{1+b}-x_{j}\right)^{2}-h_{j}\right| \leq c A_{n, j}(x)
$$

and so

$$
\begin{align*}
\left|\left(x-x_{j}\right)_{+}^{2}-Q_{j}(x)\right|< & \left|\left(x-x_{j}\right)_{+}^{2}-\gamma_{j}\left(\frac{x-\xi_{j}}{1+b}-x_{j}\right)^{2}-\gamma_{j} h_{j}\right|+c A_{n, j}(x) \\
& x \in\left(x_{j}, 1\right] . \tag{7.11}
\end{align*}
$$

Now by virtue of (7.7),

$$
\begin{aligned}
\left|\left(x-x_{j}\right)^{2}-\gamma_{j}\left(\frac{x-\xi_{j}}{1+b}-x_{j}\right)^{2}-\gamma_{j} h_{j}\right| & =\left|T_{j}(x)\right|=\left|1-\frac{\gamma_{j}}{(1+b)^{2}}\right|(1-x)^{2} \\
& <c\left(\frac{1-x}{1-x_{j}}\right)^{2}\left|I_{j}\right|^{2},
\end{aligned}
$$

hence together with (7.11), we obtain (7.6). This completes our proof.
We are ready to state the mirror of Lemma 4.

Lemma 11. Let $N \leq k<\lceil n / 2\rceil$, and assume that the nonnegative numbers $\alpha_{j}$ are such that

$$
\begin{equation*}
\sum_{j=k}^{s} \alpha_{j} \leq c \omega_{3}\left(F, \rho_{n}\left(x_{s}\right)\right), \quad s=k, \ldots,\lceil n / 2\rceil . \tag{7.12}
\end{equation*}
$$

Then for $x_{l+1}<x \leq x_{l}, l=k+1, \ldots,\lceil n / 2\rceil$, and for $x_{k+1}<x \leq 1$, for $l=k$, we have

$$
\begin{equation*}
\sum_{j=l}^{\lceil n / 2\rceil} \alpha_{j}\left(\frac{1-x}{1-x_{j}}\right)^{2} \leq \tilde{c} \omega_{3}\left(F, \rho_{n}(x)\right) \tag{7.13}
\end{equation*}
$$

Proof. The proof is a repetition of the proof of Lemma 4. We only need to observe that, instead of (4.24), we have for all $l \leq s \leq\lceil n / 2\rceil$,

$$
\frac{\rho_{n}^{3}\left(x_{s}\right)}{\rho_{n}^{3}(x)}\left(\frac{1-x}{1-x_{s}}\right)^{3 / 2} \leq 64
$$

for $x>x_{l+1}$.
We quote a lemma resembling what was done in Lemma 5.
Lemma 12 ([2, Lemma 4]). With $N$ sufficiently large, let $n>2 N+1$. Set

$$
r_{j}:=\frac{1}{26}\left(\left(x_{j}-x_{j-N}\right)^{2}+\left(x_{j}-x_{j+N}\right)^{2}\right),
$$

and put $D=20 N^{2}$.
If $\left|b_{j}\right|<\frac{r_{j}}{D\left|I_{j}\right|}$, then the linear system of equations

$$
\left\{\begin{array}{l}
\eta_{j}+\mu_{i}+v_{j}=1 \\
2 \eta_{j}\left(x_{j}-x_{j-N}\right)+2 v_{j}\left(x_{j}-x_{j+N}\right)=b_{j} \\
\eta_{j}\left(\left(x_{j}-x_{j-N}\right)^{2}+h_{j-N}\right)+\mu_{j} h_{j}+v_{j}\left(\left(x_{j}-x_{j+N}\right)^{2}+h_{j+N}\right)=r_{j}
\end{array}\right.
$$

has a unique solution $\left(\eta_{j}, \mu_{j}, v_{j}\right)$, satisfying $\eta_{j} \geq 0, \mu_{j} \geq 0$ and $v_{j} \geq 0$.
Remark 6. How big $N$ is depends on the quantities $h_{j}, 1 \leq j \leq n-1$ of Lemma 9, so that it is an absolute constant since the $Q_{j}$ 's defining the $h_{j}$ 's are fixed (see [2, Lemma 1]), so it is independent of $F$. Since we depend in our proof below on the quadratic spline of Theorem 2, we take $N \geq 1900$.

We are ready to prove Theorem 3.
Proof of Theorem 3. Recall that

$$
\begin{equation*}
\tilde{S}(x)=\tilde{P}(x)+\sum_{j=N+1}^{n-N-1} \lambda_{j}\left(x-x_{j}\right)_{+}^{2}, \tag{7.14}
\end{equation*}
$$

where $\tilde{P}:=P^{*}+\sum_{i=n-N}^{n-1} q_{i}\left(\cdot-\theta_{i}\right)^{2}+\sum_{i=n-N}^{n-1} \lambda_{i}\left(\cdot-x_{i}\right)^{2}$, is a quadratic polynomial, and that it satisfies

$$
\begin{equation*}
|F(x)-\tilde{S}(x)| \leq c \omega_{3}\left(F, \rho_{n}(x)\right) \tag{7.15}
\end{equation*}
$$

Also, by (6.5) and (4.1),

$$
\begin{equation*}
\lambda_{j} \leq c \omega_{3}\left(F,\left|I_{j}\right|\right)\left|I_{j}\right|^{-2}, \quad j=N+1, \ldots, n-N-1 \tag{7.16}
\end{equation*}
$$

Let $b_{j}, N+1 \leq j \leq n-N-1$, satisfying the requirements of Lemma 12 , to be prescribed. For the triples $\left(\eta_{j}, \mu_{j}, v_{j}\right)$, of nonnegative numbers that add up to 1 , guaranteed by Lemma 12, we define

$$
R_{n}:=\tilde{P}+\sum_{j=N+1}^{n-N-1} \lambda_{j}\left(\eta_{j} P_{j-N}+\mu_{j} P_{j}+v_{j} P_{j+N}\right)
$$

where the polynomials $P_{j}$ are from Lemma 9. Then it follows that

$$
R_{n}^{(3)}(x) \geq 0, \quad x \in[-1,1] .
$$

We will prove that

$$
\begin{equation*}
\left|\tilde{S}(x)-R_{n}(x)\right| \leq c \omega_{3}\left(F, \rho_{n}(x)\right) \tag{7.17}
\end{equation*}
$$

which combined with (7.15) yields the required estimate, proving Theorem 3 for $n>2 N+1$.
To this end, we follow (part of) the proof of [2, Theorem 1] and set

$$
\eta_{j} P_{j-N}+\mu_{j} P_{j}+v_{j} P_{j+N}-\left(\cdot-x_{j}\right)_{+}^{2}=: v_{j}+t_{j}+u_{j}
$$

where

$$
\begin{aligned}
v_{j}:= & \eta_{j}\left(P_{j-N}-h_{j-N}\left(\cdot-x_{j-N}\right)_{+}^{0}-\left(\cdot-x_{j-N}\right)_{+}^{2}\right) \\
& +\mu_{j}\left(P_{j}-h_{j}\left(\cdot-x_{j}\right)_{+}^{0}-\left(\cdot-x_{j}\right)_{+}^{2}\right) \\
& +v_{j}\left(P_{j+N}-h_{j+N}\left(\cdot-x_{j+N}\right)_{+}^{0}-\left(\cdot-x_{j+N}\right)_{+}^{2}\right) \\
t_{j}:= & \eta_{j}\left(\left(\cdot-x_{j-N}\right)_{+}^{2}-2\left(x_{j}-x_{j-N}\right)\left(\cdot-x_{j}\right)_{+}\right. \\
& \left.-\left(x_{j}-x_{j-N}\right)^{2}\left(\cdot-x_{j}\right)_{+}^{0}-\left(\cdot-x_{j}\right)_{+}^{2}\right) \\
& +v_{j}\left(\left(\cdot-x_{j+N}\right)_{+}^{2}-2\left(x_{j}-x_{j+N}\right)\left(\cdot-x_{j}\right)_{+}\right. \\
& \left.-\left(x_{j}-x_{j+N}\right)^{2}\left(\cdot-x_{j}\right)_{+}^{0}-\left(\cdot-x_{j}\right)_{+}^{2}\right) \\
& +\eta_{j} h_{j-N}\left(\left(\cdot-x_{j-N}\right)_{+}^{0}-\left(\cdot-x_{j}\right)_{+}^{0}\right)+v_{j} h_{j+N}\left(\left(\cdot-x_{j+N}\right)_{+}^{0}-\left(\cdot-x_{j}\right)_{+}^{0}\right),
\end{aligned}
$$

and

$$
u_{j}:=r_{j}\left(\cdot-x_{j}\right)_{+}^{0}+b_{j}\left(\cdot-x_{j}\right)_{+},
$$

where $r_{j}$ and $b_{j}$ are from Lemma 12.
In order to derive the estimate for $v_{j}(x)$, we have by virtue of Lemma 9 ,

$$
\begin{equation*}
\left|v_{j}(x)\right| \leq c\left(A_{n, j-N}(x)+A_{n, j}(x)+A_{n, j+N}(x)\right) \tag{7.18}
\end{equation*}
$$

Fix $x \in[-1,1]$ and separate the sum

$$
\sum_{j=N+1}^{n-N-1} \lambda_{j}\left|v_{j}(x)\right|=\sum_{j: \rho_{n}(x) \leq\left|I_{j}\right|} \lambda_{j}\left|v_{j}(x)\right|+\sum_{j: \rho_{n}(x)>\left|I_{j}\right|} \lambda_{j}\left|v_{j}(x)\right|=: \sum^{\prime}+\sum^{\prime \prime}
$$

For $j$ that satisfy $\left|I_{j}\right| \geq \rho_{n}(x)$, we have by (7.16),

$$
\begin{aligned}
\lambda_{j} & \leq c \omega_{3}\left(F,\left|I_{j}\right|\right)\left|I_{j}\right|^{-2} \leq c\left(\frac{\left|I_{j}\right|}{\rho_{n}(x)}+1\right)^{3}\left|I_{j}\right|^{-2} \omega_{3}\left(F, \rho_{n}(x)\right) \\
& =c \frac{\omega_{3}\left(F, \rho_{n}(x)\right)}{\rho_{n}^{3}(x)}\left(1+\frac{\rho_{n}(x)}{\left|I_{j}\right|}\right)^{3}\left|I_{j}\right| \\
& \leq c \frac{\omega_{3}\left(F, \rho_{n}(x)\right)}{\rho_{n}^{3}(x)}\left|I_{j}\right| .
\end{aligned}
$$

Also, in view of (4.3),

$$
\lambda_{j} \leq c \frac{\omega_{3}\left(F, \rho_{n}(x)\right)}{\rho_{n}^{3}(x)} \min \left\{\left|I_{j-N}\right|,\left|I_{j+N}\right|\right\} .
$$

Therefore, by (7.18)

$$
\begin{align*}
\sum^{\prime} \leq & \sum^{\prime} c \lambda_{j} \rho_{n}^{8.5}(x)\left(\frac{1}{\left(\rho_{n}(x)+\left|x-x_{j-N}\right|\right)^{6.5}}\right. \\
& \left.+\frac{1}{\left(\rho_{n}(x)+\left|x-x_{j}\right|\right)^{6.5}}+\frac{1}{\left(\rho_{n}(x)+\left|x-x_{j+N}\right|\right)^{6.5}}\right) \\
\leq & c \omega_{3}\left(F, \rho_{n}(x)\right) \rho_{n}^{5.5}(x) \sum_{j=1}^{n-1} \frac{\left|I_{j}\right|}{\left(\rho_{n}(x)+\left|x-x_{j}\right|\right)^{6.5}} \\
\leq & c \omega_{3}\left(F, \rho_{n}(x)\right) \rho_{n}^{5.5}(x) \int_{\rho_{n}(x)}^{\infty} \frac{d u}{u^{6.5}}<c \omega_{3}\left(F, \rho_{n}(x)\right) \tag{7.19}
\end{align*}
$$

For the other sum, note that if $\left|I_{j}\right|<\rho_{n}(x)$, then $\omega_{3}\left(F,\left|I_{j}\right|\right)<c \omega_{3}\left(F, \rho_{n}(x)\right)$. Also by (4.3), $\left|I_{j}\right| \leq c \min \left\{\left|I_{j-N}\right|,\left|I_{j+N}\right|\right\}$. Hence, together with (7.16) and (7.18) we obtain,

$$
\begin{align*}
\sum^{\prime \prime} \leq & c \omega_{3}\left(F, \rho_{n}(x)\right) \rho_{n}^{2}(x) \sum^{\prime \prime}\left[\frac{\left|I_{j-N}\right|}{\left(\rho_{n}(x)+\left|x-x_{j-N}\right|\right)^{3}}\right. \\
& \left.+\frac{\left|I_{j}\right|}{\left(\rho_{n}(x)+\left|x-x_{j}\right|\right)^{3}}+\frac{\left|I_{j+N}\right|}{\left(\rho_{n}(x)+\left|x-x_{j+N}\right|\right)^{3}}\right] \\
\leq & c \omega_{3}\left(F, \rho_{n}(x)\right) \rho_{n}^{2}(x) \sum_{j=1}^{n-1} \frac{\left|I_{j}\right|}{\left(\rho_{n}(x)+\left|x-x_{j}\right|\right)^{3}} \\
\leq & c \omega_{3}\left(F, \rho_{n}(x)\right) \rho_{n}^{2}(x) \int_{\rho_{n}(x)}^{\infty} \frac{d u}{u^{3}}<c \omega_{3}\left(F, \rho_{n}(x)\right) . \tag{7.20}
\end{align*}
$$

Thus, combining (7.19) and (7.20), we obtain

$$
\begin{equation*}
\sum_{j=N+1}^{n-N-1} \lambda_{j}\left|v_{j}(x)\right|<c \omega_{3}\left(F, \rho_{n}(x)\right) \tag{7.21}
\end{equation*}
$$

At the same time the support of the function $t_{j}$ is contained in $\left[x_{j+N}, x_{j-N}\right]$, so that for $x \in I_{i}, 1 \leq i \leq n$,

$$
\sum_{j=N+1}^{n-N-1} \lambda_{j}\left|t_{j}(x)\right|=\sum_{\max \{N+1, i-N\}}^{\min \{n-N, i+N-1\}} \lambda_{j}\left|t_{j}(x)\right|
$$

$$
\begin{equation*}
\leq c \sum_{\max \{N+1, i-N\}}^{\min \{n-N-1, i+N-1\}} \omega_{3}\left(F, \rho_{n}\left(x_{j}\right)\right) \leq c \omega_{3}\left(F, \rho_{n}(x)\right), \tag{7.22}
\end{equation*}
$$

since $\left|t_{j}(x)\right| \leq c\left|I_{j}\right|^{2}$ and we applied (7.16), and by (4.1) and (4.2),

$$
\begin{aligned}
& \omega_{3}\left(F, \rho_{n}\left(x_{j}\right)\right) \leq c \omega_{3}\left(F, \rho_{n}(x)\right) \\
& \max \{N+1, i-N\} \leq j \leq \min \{n-N-1, i+N-1\}
\end{aligned}
$$

Finally, we estimate $\sum_{j=N+1}^{n-N-1} \lambda_{j} u_{j}$. To this end, we have the piecewise constant

$$
\sum_{j=N+1}^{n-N-1} \alpha_{j}\left(x-x_{j}\right)_{+}^{0},
$$

with $0 \leq \alpha_{j}:=\lambda_{j} r_{j} \leq c \omega_{3}\left(F, \rho_{n}\left(x_{j}\right)\right)$ (see (7.16)). We repeat what we have done in the proof of Lemma 7. We deal separately with the summation on $j \geq\left\lceil\frac{n}{2}\right\rceil$ and with the rest. We begin with $k_{1}=n-N-1$ and (if possible) find $s_{1}<k_{1}$ such that the conditions of Lemma 3 are satisfied for the pair ( $s_{1}, k_{1}$ ). Then we take $k_{2}=s_{1}-1$ and find $s_{2}<k_{2}$ with similar properties. If after a few steps, we arrive at $\left\lceil\frac{n}{2}\right\rceil=s_{m}<k_{m}$, with the pair $\left(s_{m}, k_{m}\right)$ satisfying the conditions of Lemma 3, we are done. Otherwise, the process stops, that is, we have an index $k \leq n-N-1$ (which again may be $k=k_{1}$ ), such that

$$
\begin{equation*}
\sum_{j=s}^{k} \alpha_{j} \leq C D \omega_{3}\left(F, \rho_{n}\left(x_{s}\right)\right), \quad s=\lceil n / 2\rceil, \ldots, k \tag{7.23}
\end{equation*}
$$

We go through a similar process for the other summation, that is, for $j \leq\lceil n / 2\rceil$. Again, this process may end with $s_{m^{\prime}}^{\prime}=\lceil n / 2\rceil$, in which case we are done, or we may have an index $k^{\prime} \geq N+1$ such that,

$$
\begin{equation*}
\sum_{j=k^{\prime}}^{s^{\prime}} \alpha_{j} \leq C D \omega_{3}\left(F, \rho_{n}\left(x_{s^{\prime}}\right)\right), \quad s^{\prime}=k^{\prime}, \ldots,\lceil n / 2\rceil . \tag{7.24}
\end{equation*}
$$

For the sums of the former type we obtain by the same proof as of Lemma 7, non decreasing piecewise linear functions

$$
\sum_{j=k_{1}}^{s_{m}} \beta_{j}\left(x-x_{j}\right)_{+} \quad \text { and } \quad \sum_{j=s_{m^{\prime}}^{\prime}}^{k_{1}^{\prime}} \beta_{j}\left(x-x_{j}\right)_{+}
$$

such that

$$
\left\lvert\, \begin{array}{r}
\left\{\sum_{j=N+1}^{s_{m^{\prime}}^{\prime}}+\sum_{j=s_{m}}^{n-N-1}\right\}\left(\alpha_{j}\left(x-x_{j}\right)_{+}^{0}-\beta_{j}\left(x-x_{j}\right)_{+}\right) \mid \leq \\
x \in\left[\begin{array}{c} 
\\
x \in[-1,1]
\end{array}\right.
\end{array}\right.
$$

with $\left|\beta_{j}\right|<\frac{\alpha_{j}}{D\left|I_{j}\right|}$.
Thus, with $b_{j}$ defined by $\lambda_{j} b_{j}:=\beta_{j}, j=k_{1}, \ldots, s_{m}$ and $j=s_{m^{\prime}}^{\prime}, \ldots, k_{1}^{\prime}$,

$$
\begin{equation*}
\left|\left\{\sum_{j=N+1}^{s_{m^{\prime}}^{\prime}}+\sum_{j=s_{m}}^{n-N-1}\right\} \lambda_{j} u_{j}(x)\right| \leq c D \omega_{3}\left(F, \rho_{n}(x)\right), \quad x \in[-1,1] . \tag{7.25}
\end{equation*}
$$

Now, we have to deal with the remaining elements, that is, those in (7.23) and (7.24). We go back to the basic representation (7.14) and replace the truncated powers $\left(x-x_{j}\right)_{+}^{2}, j=k^{\prime}, \ldots,\lceil n / 2\rceil$, by the polynomials of Lemma 10. One should note that unlike the spline case (see Lemma 6), the polynomials do not coincide with the truncated powers $\left(x-x_{j}\right)_{+}^{2}$ on $\left[-1, x_{j}\right]$, and that our estimates on $\left(x_{j}, 1\right]$ do not involve only the terms $\left((1-x)^{2} /\left(1-x_{j}\right)^{2}\right)\left|I_{j}\right|^{2}$, but also the terms $A_{n, j}(x)$. The sum of the terms $A_{n, j}(x)$ is dealt with by the same proof for the $v_{j}$ 's (see (7.19) and (7.20)), and we estimate the sum of the terms $\left((1-x)^{2} /\left(1-x_{j}\right)^{2}\right)\left|I_{j}\right|^{2}$, as in the proof of Lemma 7. Hence, we obtain for this sum, the required estimate by Lemma 11. Finally, we apply (5.14) to move the truncated powers $\left(x-x_{j}\right)_{+}^{2}, j=\lceil n / 2\rceil, \ldots, k$ to the interval [0,1], and similarly obtain the approximating polynomials and the required estimates as explained above. So, we summarize that

$$
\begin{equation*}
\left|\left\{\sum_{j=\lceil n / 2\rceil}^{k}+\sum_{j=k^{\prime}}^{\lceil n / 2\rceil}\right\} u_{j}(x)\right| \leq c \omega_{3}\left(F, \rho_{n}(x)\right), \quad x \in[-1,1] . \tag{7.26}
\end{equation*}
$$

Combining (7.21) and (7.22), (7.25) and (7.26), we obtain (7.17). We complete the proof for $2 \leq n \leq 2 N+1$, by taking the interpolating quadratic we took in the proof of Theorem 2. This completes the proof.
