# WIDTHS AND SHAPE-PRESERVING WIDTHS OF SOBOLEV-TYPE CLASSES OF $s$-MONOTONE FUNCTIONS 

J. Gilewicz, V. N. Konovalov and D. Leviatan ${ }^{1}$

#### Abstract

Let $I$ be a finite interval, $r, n \in \mathbb{N}, s \in \mathbb{N}_{0}$ and $1 \leq p \leq \infty$. Given a set $M$, of functions defined on $I$, denote by $\Delta_{+}^{s} M$ the subset of all functions $y \in M$ such that the $s$-difference $\Delta_{\tau}^{s} y(\cdot)$ is nonnegative on $I, \forall \tau>0$. Further, denote by $W_{p}^{r}$ the Sobolev class of functions $x$ on $I$ with the seminorm $\left\|x^{(r)}\right\|_{L_{p}} \leq 1$. We obtain the exact orders of the Kolmogorov and the linear widths, and of the shape-preserving widths of the classes $\Delta_{+}^{s} W_{p}^{r}$ in $L_{q}$ for $s>r+1$ and $(r, p, q) \neq(1,1, \infty)$. We show that while the widths of the classes depend in an essential way on the parameter $s$, which characterizes the shape of functions, the shape-preserving widths of these classes remain asymptotically $\asymp n^{-2}$.

## 1. Introduction, preliminaries, and the main result

Let $X$ be a real linear space of vectors $x$ with norm $\|x\|_{X}$, and $W$ and $M$ be nonempty subsets of $X$. The deviation of $W$ from $M$ is defined by

$$
E(W, M)_{X}:=\sup _{x \in W} \inf _{y \in M}\|x-y\|_{X} .
$$

The Kolmogorov $n$-width of $W$ is defined by

$$
d_{n}(W)_{X}^{\text {kol }}:=\inf _{M^{n}} E\left(W, M^{n}\right)_{X}, \quad n \geq 0
$$

where the infimum is taken over all affine subsets $M^{n}$ of dimension $\leq n$.
For a nonempty subset $V \subseteq X$, we denote the relative $n$-width of Kolmogorov-type of the set $W$, subject to the constraint $V$, by

$$
d_{n}(W, V)_{X}^{k o l}:=\inf _{M^{n}} E\left(W, M^{n} \cap V\right)_{X}, \quad n \geq 0
$$

where the infimum is taken over all affine subsets $M^{n}$ of dimension $\leq n$ such that $M^{n} \cap V \neq \emptyset$. Obviously, $d_{n}(W, X)_{X}^{\text {kol }}=d_{n}(W)_{X}^{\text {kol }}$ and, in general, $d_{n}(W, V)_{X}^{\text {kol }} \geq d_{n}(W)_{X}^{\text {kol }}$.

[^0]If $L \subseteq X$ is a linear subspace, we may look at the deviation of $W$ from continuous linear images of $\operatorname{span}(W)$ into $L$. Namely, we define

$$
E(W, L)_{X}^{l i n}:=\inf _{A} \sup _{x \in W}\|x-A x\|_{X}
$$

where the infimum is taken over all continuous linear operators on $\operatorname{span}(W)$, such that $A: \operatorname{span}(W) \mapsto L$.
The linear $n$-width of $W$ is defined by

$$
d_{n}(W)_{X}^{l i n}:=\inf _{L^{n}} E\left(W, L^{n}\right)_{X}^{l i n}, \quad n \geq 0
$$

where the infimum is taken over all linear subspaces $L^{n} \subseteq X$, of dimension $\leq n$. Obviously,

$$
d_{n}(W)_{X}^{k o l} \leq d_{n}(W)_{X}^{l i n} .
$$

Let $I:=(-1,1)$, and let $x$ be a function defined on $I$. For an integer $s \geq 0$, set

$$
\Delta_{\tau}^{s} x(t):=\left\{\begin{array}{l}
\sum_{k=0}^{s}(-1)^{s-k}\binom{s}{k} x(t+k \tau), \quad(t, t+s \tau) \subseteq I \\
0, \quad \text { otherwise },
\end{array}\right.
$$

the $s$-th difference of the function $x$, with step $\tau>0$. A function $x$ is called $s$-monotone on $I$ if $\Delta_{\tau}^{s} x(t) \geq 0, t \in I$, for all $\tau>0$. It is well known that if $x$ is $s$-monotone on $I, s \geq 2$, then $x^{(s-2)}$ is locally absolutely continuous in $I$, (notation $x^{(s-2)} \in A C_{l o c}(I)=: A C_{l o c}$ ), and $x^{(s-1)}$ is nondecreasing there (see [B], [PPT], and [RV], for various properties of $s$-monotone functions). Given a function space $X$, and $W \subseteq X$, as above, we denote by $\Delta_{+}^{s} W$ the subset of $s$-monotone functions $x \in W$.

Finally, for $1 \leq p \leq \infty$, we denote by $L_{p}=L_{p}(I)$ the usual $L_{p}$-spaces, and for an integer $r \geq 1$, we denote the Sobolev class

$$
W_{p}^{r}:=W_{p}^{r}(I):=\left\{x \mid x^{(r-1)} \in A C_{l o c},\left\|x^{(r)}\right\|_{L_{p}} \leq 1\right\}
$$

For $1 \leq q \leq \infty$, we call the relative width $d_{n}\left(\Delta_{+}^{s} W_{p}^{r}, \Delta_{+}^{s} L_{q}\right)_{X}^{k o l}$, the shape-preserving $n$ width of the class $\Delta_{+}^{s} W_{p}^{r}$ in $L_{q}$.

The asymptotic behavior of the Kolmogorov and linear $n$-widths of the Sobolev classes $W_{p}^{r}$ in $L_{q}, 1 \leq q \leq \infty$, is well known. Recently Konovalov and Leviatan, [KL1], have investigated the behavior of the Kolmogorov and linear widths in $L_{q}$ of the smaller classes $\Delta_{+}^{s} W_{p}^{r}, 0 \leq s \leq r+1$. Among the results they proved that in most cases the Kolmogorov and linear $n$-widths of the smaller classes are asymptotically the same as those of the class $W_{p}^{r}$. Namely, the behavior in the typical case when $0 \leq s \leq r$, and $1 \leq p, q \leq \infty$ are such that $(r, p, q) \neq(1,1, \infty)$, is that if $(r, p) \neq(1,1)$, and if $(r, p)=(1,1)$ and $1 \leq q \leq 2$, then

$$
d_{n}\left(\Delta_{+}^{s} W_{p}^{r}\right)_{L_{q}}^{k o l} \asymp d_{n}\left(W_{p}^{r}\right)_{L_{q}}^{k o l} \asymp n^{-r+(\max \{1 / p, 1 / 2\}-\max \{1 / q, 1 / 2\})_{+}}, \quad n \geq r .
$$

Here and in the sequel $(a)_{+}:=\max \{a, 0\}$ and the notation $a_{n} \asymp b_{n}$ means that there exist constants $0<c_{*}<c^{*}$, such that $c_{*} a_{n} \leq b_{n} \leq c^{*} a_{n}, \forall n$.

The situation is much different for the class $\Delta_{+}^{r+1} W_{p}^{r}$. Namely (see [KL1],

Theorem A. Let $r \geq 1$, and let $1 \leq p, q \leq \infty$ be such that $(r, p, q) \neq(1,1, \infty)$. Then

$$
d_{n}\left(\Delta_{+}^{r+1} W_{p}^{r}\right)_{L_{q}}^{k o l} \asymp d_{n}\left(\Delta_{+}^{r+1} W_{p}^{r}\right)_{L_{q}}^{l i n} \asymp n^{-r-1+\min \left\{1 / q^{\prime}, 1 / 2\right\}}, \quad n>r
$$

where $1 / q+1 / q^{\prime}=1$.
Thus, both $n$-widths of $\Delta_{+}^{r+1} W_{p}^{r}$ are asymptotically much smaller than those of $W_{p}^{r}$.
We are going to show that the new pattern prevails when $s>r+1$. We will show that the asymptotic order of both $n$-widths of $\Delta_{+}^{s} W_{p}^{r}, s>r+1$, decrease with $s$ (increasing). Specifically, we prove the following result.

Theorem 1. Let $r$ and $s$ be integers such that $s>r+1 \geq 2$, and let $1 \leq p, q \leq \infty$ be such that $(r, p, q) \neq(1,1, \infty)$. Then

$$
\begin{equation*}
d_{n}\left(\Delta_{+}^{s} W_{p}^{r}\right)_{L_{q}}^{k o l} \asymp d_{n}\left(\Delta_{+}^{s} W_{p}^{r}\right)_{L_{q}}^{l i n} \asymp n^{-s+\min \left\{1 / q^{\prime}, 1 / 2\right\}}, \quad n \geq s \tag{1.1}
\end{equation*}
$$

Remarks. (i) It is interesting to note that the upper bounds are achieved by piecewise polynomials of degree $s-1$, with $n$ prescribed knots, that are elements of $\Delta_{+}^{s} C^{s-2}$.
(ii) We emphasize that given $x \in \Delta_{+}^{s} W_{p}^{r}, s>r$, we cannot, in general, guarantee the finiteness of the norms of the derivatives of order $>r$, in any of the spaces $L_{q}$. (Still when $p=\infty, x^{(r+1)} \in L_{1}$.) Also note that for $s>r$ the asymptotic orders of the Kolmogorov and linear widths in $L_{q}$ of the classes $\Delta_{+}^{s} W_{p}^{r}$ depend in an essential way on the parameter $s$, which characterizes the shape of the functions, while they do not depend on $r$ and $p$.
(iii) Perhaps one should also point out that also for $s \leq r$, we need $s \leq r-1 / p+1 / q$ to guarantee that $x^{(s)} \in L_{q}$.

Konovalov and Leviatan, [KL2, KL3], investigated also the behavior of the shape-preserving widths of the classes $\Delta_{+}^{s} W_{p}^{r}$ for $0 \leq s \leq r+1$. Among the results,
Theorem B. Let $r \geq 1$ and let $1 \leq p, q \leq \infty$ be such that $(r, p, q) \neq(1,1, \infty)$. Then if $(r, p) \neq(1,1)$, and if $(r, p)=(1,1)$ and $1 \leq q \leq 2$, we have

$$
d_{n}\left(\Delta_{+}^{0} W_{p}^{r}, \Delta_{+}^{0} L_{q}\right)_{L_{q}}^{k o l} \asymp n^{-r+(\max \{1 / p, 1 / 2\}-\max \{1 / q, 1 / 2\})_{+}}, \quad n \geq r
$$

Also, if $1 \leq s \leq \min \{2, r\}$, then

$$
d_{n}\left(\Delta_{+}^{1} W_{p}^{r}, \Delta_{+}^{1} L_{q}\right)_{L_{q}}^{k o l} \asymp n^{-r+(1 / p-1 / q)_{+}}, \quad n \geq r,
$$

and if $s=2$ and $r=1$, then

$$
d_{n}\left(\Delta_{+}^{2} W_{p}^{1}, \Delta_{+}^{2} L_{q}\right)_{L_{q}}^{k o l} \asymp n^{-1-1 / q}, \quad n \geq 1
$$

Finally, if $3 \leq s \leq r$, then

$$
d_{n}\left(\Delta_{+}^{s} W_{p}^{r}, \Delta_{+}^{s} L_{q}\right)_{L_{q}}^{k o l} \asymp n^{-r+s+1 / p-3}, \quad n \geq r
$$

On the other hand, it was shown in [KL3] that,

Theorem C. Let $r>1$, and let $1 \leq p, q \leq \infty$. Then

$$
d_{n}\left(\Delta_{+}^{r+1} W_{p}^{r}, \Delta_{+}^{r+1} L_{q}\right)_{L_{q}}^{k o l} \asymp n^{-2}, \quad n>r .
$$

We are going to show that for all $s>r+1$, the shape-preserving widths of $\Delta_{+}^{s} W_{p}^{r}$ in $L_{q}$, asymptotically are independent of any of the parameters, $p, q, r$ and $s$, and that all are of the asymptotic order $n^{-2}$. Namely,

Theorem 2. Let $r$ and $s$ be integers such that $s>r+1$, and let $1 \leq p, q \leq \infty$ be such that $(r, p, q) \neq(1,1, \infty)$. Then

$$
\begin{equation*}
d_{n}\left(\Delta_{+}^{s} W_{p}^{r}, \Delta_{+}^{s} L_{q}\right)_{L_{q}}^{k o l} \asymp n^{-2}, \quad n \geq s \tag{1.2}
\end{equation*}
$$

Remark. Again, the upper bounds are achieved by piecewise polynomials of degree $s-1$, with $n$ prescribed knots, that are elements of $\Delta_{+}^{s} C^{s-2}$.

The rest paper is divided into five sections. First in Section 2 we have some auxiliary lemmas and we reduce the question of the upper bounds to a simpler case. The next three are devoted to proving our claims for the upper bounds, and finally we prove the lower bounds in Section 6.

## 2. Auxiliary lemmas and reduction to subcollections

For $m \geq 2$ and $k \in \mathbb{Z}$ let $(k)_{m}:=\binom{m-2+k}{m-1}$, and note that

$$
\begin{equation*}
(k)_{m}=\psi_{m}(k), \quad k \geq-m+2 \tag{2.1}
\end{equation*}
$$

where

$$
\begin{equation*}
\psi_{m}(t):=((m-1)!)^{-1} \prod_{l=1}^{m-1}(t+l-1), \quad t \in \mathbb{R} \tag{2.2}
\end{equation*}
$$

and that

$$
\begin{equation*}
(k)_{m} \leq k^{m-1} \quad k \geq 1 \tag{2.3}
\end{equation*}
$$

Our first lemma is
Lemma 1. The following two systems of linear equations are equivalent

$$
\begin{equation*}
\tilde{\omega}_{i}=\sum_{j=1}^{i}(i-j+1)_{m} \omega_{j}, \quad i=1, \ldots, n \tag{2.4}
\end{equation*}
$$

and

$$
\begin{equation*}
\sum_{k=1}^{i}(-1)^{i-k}\binom{m}{i-k} \tilde{\omega}_{k}=\omega_{i}, \quad i=1, \ldots, n \tag{2.5}
\end{equation*}
$$

Proof. Let $1 \leq i \leq n$. We substitute (2.4) in (2.5) and get by (2.1) and (2.2),

$$
\begin{aligned}
\sum_{k=1}^{i}(-1)^{i-k}\binom{m}{i-k} \tilde{\omega}_{k} & =\sum_{k=1}^{i}(-1)^{i-k}\binom{m}{i-k} \sum_{j=1}^{k}(k-j+1)_{m} \omega_{j} \\
& =\sum_{j=1}^{i}\left(\sum_{k=j}^{i}(-1)^{i-k}\binom{m}{i-k}(k-j+1)_{m}\right) \omega_{j} \\
& =\sum_{j=1}^{i}\left(\sum_{k=0}^{i-j}(-1)^{k}\binom{m}{k}(i-k-j+1)_{m}\right) \omega_{j} \\
& =\sum_{j=1}^{i}\left(\sum_{k=0}^{i-j}(-1)^{k}\binom{m}{k} \psi_{m}(i-k-j+1)\right) \omega_{j}=: \Sigma .
\end{aligned}
$$

Now, if $i>j$, then

$$
\sum_{k=0}^{i-j}(-1)^{k}\binom{m}{k} \psi_{m}(i-k-j+1)=\sum_{k=0}^{m}(-1)^{k}\binom{m}{k} \psi_{m}(i-k-j+1)=0
$$

where the right equality follows since $\psi_{m}$ is a polynomial of degree $<m$. For the left equality we observe that if $m<k \leq i-j$, then $\binom{m}{k}=0$, and if $1 \leq i-j<k \leq m$, then $1>i-j-k+1 \geq-m+2$ so that $\psi_{m}(i-k-j+1)=0$.

For $i=j$

$$
\sum_{k=0}^{i-j}(-1)^{k}\binom{m}{k} \psi_{m}(i-k-j+1)=1
$$

Hence, $\Sigma=\omega_{i}$ and the proof is complete.
Our next result follows immediately by Lemma 1.
Lemma 2. Given $a, b \in \mathbb{R}^{n-1}$ such that $b$ has nonzero entries. Let $1 \leq p \leq \infty$ and $M \geq 0$, and let

$$
\Omega_{m}(b):=\left\{\omega \in \mathbb{R}^{n-1} \mid\|\tilde{\omega}\|_{\ell_{p}} \leq M, \quad \tilde{\omega}_{i}:=b_{i} \sum_{j=1}^{i}(i-j+1)_{m} \omega_{j}, \quad i=1, \ldots, n-1\right\} .
$$

Then,

$$
\max _{\omega \in \Omega_{m}(b)}|\langle a, \omega\rangle|=M\|c\|_{\ell_{p^{\prime}}}, \quad c_{i}:=b_{i}^{-1} \sum_{k=0}^{n-i-1}(-1)^{k}\binom{m}{k} a_{i+k}, \quad i=1, \ldots, n-1,
$$

where $1 / p+1 / p^{\prime}=1$, and where $\langle a, \omega\rangle:=\sum_{i=1}^{n-1} a_{i} \omega_{i}$.
Proof. By Lemma 1, the operator $T: \mathbb{R}^{n-1} \mapsto \mathbb{R}^{n-1}$, define by $\tilde{\omega}=T \omega$, where

$$
\tilde{\omega}_{i}:=b_{i} \sum_{j=1}^{i}(i-j+1)_{m} \omega_{j}, \quad i=1, \ldots, n-1,
$$

is invertible. Hence,

$$
\begin{aligned}
\max _{\omega \in \Omega_{m}(b)}|\langle a, \omega\rangle| & =\max _{\|T \omega\|_{\ell_{p}} \leq M}|\langle a, \omega\rangle| \\
& =\max _{\|\tilde{\omega}\|_{\ell_{p} \leq M}}\left|\left\langle T^{-1^{*}} a, \tilde{\omega}\right\rangle\right| \\
& =M\left\|T^{-1^{*}} a\right\|_{\ell_{p^{\prime}}}=M\|c\|_{\ell_{p^{\prime}}}
\end{aligned}
$$

This completes the proof.
Recall that if $x$ is $s$-monotone, then $x^{(s-1)}$ is nondecreasing, thus it has left and right derivatives $x_{-}^{(s-1)}(\tau)$ and $x_{+}^{(s-1)}(\tau), \tau \in I$. We set $x^{(s-1)}(\tau):=\left(x_{+}^{(s-1)}(\tau)+x_{-}^{(s-1)}(\tau)\right) / 2$, and let

$$
\begin{equation*}
\pi_{s}(t ; x ; \tau):=\sum_{k=0}^{s-1} \frac{x^{(k)}(\tau)}{k!}(t-\tau)^{k}, \quad t \in I \tag{2.6}
\end{equation*}
$$

denote the Taylor polynomial of $x$ about $\tau$.
Given $x \in \Delta_{+}^{s} W_{p}^{r}$, let

$$
\tilde{x}(t):=x(t)-\pi_{s}(t ; x ; 0), \quad t \in I
$$

Then

$$
\tilde{x}^{(k)}(0)=0, \quad k=0, \ldots, s-1
$$

and it is easy to verify that $\tilde{x}^{(k)}(t) \geq 0, t \in I_{+}:=[0,1)$, and $(-1)^{s-k} \tilde{x}^{(k)}(t) \geq 0, t \in I_{-}:=$ $(-1,0], k=0, \ldots, s-1$. In particular all derivatives $\tilde{x}^{(k)}, k=0, \ldots, s-1$, are nondecreasing on $I_{+}$, while on $I_{-}$the derivatives $\tilde{x}^{(k)}, k=0, \ldots, s-1$, alternate in monotonicity. Moreover, Konovalov and Leviatan have proved in [KL4, Lemma 2] that

$$
\begin{equation*}
\left\|\tilde{x}^{(r)}\right\|_{L_{p}(I)} \leq c\left\|x^{(r)}\right\|_{L_{p}(I)} \tag{2.7}
\end{equation*}
$$

where $c=c(s, p)$.

Hence, if we restrict our discussion to $I_{+}$, and if we are able to construct piecewise polynomials $\sigma_{s, n}(t ; \tilde{x})$, of degree $s-1$ and with $n \geq 1$ knots, such that

$$
\begin{equation*}
\left\|\tilde{x}(\cdot)-\sigma_{s, n}(\cdot ; \tilde{x})\right\|_{L_{q}\left(I_{+}\right)} \leq c n^{-\alpha}\left\|\tilde{x}^{(r)}\right\|_{L_{p}(I)} \tag{2.8}
\end{equation*}
$$

where $c$ is an absolute constant independent of $n$, and $\alpha>0$, then the same estimates for $I_{-}$follow by taking $\sigma_{s, n}(t ; \tilde{x}):=(-1)^{s} \sigma_{s, n}(-t ; y), t \in I_{-}$, where $y(t):=(-1)^{s} \tilde{x}(-t), t \in I$, since the latter satisfies $y^{(k)}(t)=(-1)^{s-k} \tilde{x}^{(k)}(-t) \geq 0, t \in I_{-}, k=0, \ldots, s-1$.

Therefore, we fix $n \geq 1$, and $\beta \geq 1$, and denote

$$
t_{i}:=t_{n, i}:=t_{\beta, n, i}:= \begin{cases}1-((n-i) / n)^{\beta}, & i=0,1, \ldots, n  \tag{2.9}\\ -1+((n+i) / n)^{\beta}, & i=-1, \ldots,-n\end{cases}
$$

and

$$
I_{i}:=I_{n, i}:=I_{\beta, n, i}:= \begin{cases}{\left[t_{\beta, n, i-1}, t_{\beta, n, i}\right),} & i=1, \ldots, n \\ \left(t_{\beta, n, i}, t_{\beta, n, i+1}\right], & i=-1, \ldots,-n .\end{cases}
$$

In Sections 3 and 5, we will construct various piecewise polynomials $\sigma_{s, n}(t ; \tilde{x}), t \in I_{+}$, of degree $s$ having knots at $t_{n, i}, 1 \leq i<n$, satisfying (2.8) for various $\alpha$ 's. Then

$$
\sigma_{s, n}(t ; \tilde{x}):= \begin{cases}\sigma_{s, n}(t ; \tilde{x}) & t \in I_{+} \\ (-1)^{s} \sigma_{s, n}(-t ; y), & t \in I_{-}\end{cases}
$$

satisfies

$$
\left\|\tilde{x}(\cdot)-\sigma_{s, n}(\cdot ; \tilde{x})\right\|_{L_{q}(I)} \leq c n^{-\alpha}\left\|\tilde{x}^{(r)}\right\|_{L_{p}(I)}
$$

Hence, setting

$$
\sigma_{s, n}(t ; x):=\sigma_{s, n}(t ; \tilde{x})+\pi_{s}(t ; x ; 0), \quad t \in I
$$

by virtue of (2.7), yields

$$
\begin{aligned}
\left\|x(\cdot)-\sigma_{s, n}(\cdot ; x)\right\|_{L_{q}(I)} & =\left\|\tilde{x}(\cdot)-\sigma_{s, n}(\cdot ; \tilde{x})\right\|_{L_{q}(I)} \\
& \leq c\left\|\tilde{x}^{(r)}\right\|_{L_{p}(I)} n^{-\alpha} \\
& \leq c\left\|x^{(r)}\right\|_{L_{p}(I)} n^{-\alpha}
\end{aligned}
$$

If we denote by $\Sigma_{s, n}:=\Sigma_{\beta, s, n}(I)$, the space of piecewise polynomials $\sigma: I \rightarrow \mathbb{R}$, of order $s$ (of degree $s-1$ ), with knots at $t_{\beta, n, i}, i= \pm 1, \ldots, \pm(n-1)$ (for $n=1$, this is just the space of polynomials of degree $s-1$ ), then $\operatorname{dim} \Sigma_{s, n}=s(2 n-1)$, and for $x \in \Delta_{+}^{s} W_{p}^{r}$, clearly $\sigma_{s}(\cdot ; x) \in \Sigma_{s, n}$.

Therefore, in Sections 3 through 5 we are going to assume that $x \in \Delta_{+}^{s} W_{p}^{r}$ satisfies

$$
\begin{equation*}
x^{(k)}(0)=0, \quad k=0, \ldots, s-1 \tag{2.10}
\end{equation*}
$$

so that, in particular $x^{(k)}(t) \geq 0, t \in I_{+}$, and all derivatives $x^{(k)}, k=0, \ldots, s-1$, are nondecreasing on $I_{+}$.

## 3. Theorem 1, the upper bounds: Crude estimates

In view of the above, this section is devoted to proving that an $x \in \Delta_{+}^{s} W_{p}^{r}$ which satisfies (2.10) can be well approximated by piecewise polynomials associated with it, in a linear fashion, on $I_{+}$. But the estimates will only be best possible for a restricted range of $q$. Specifically, we will show that there is an $s$-monotone piecewise polynomial with $2 n-2$ prescribed knots $\sigma_{s, n}(\cdot ; x)$ (see construction below), such that

$$
\begin{equation*}
\left\|x(\cdot)-\sigma_{s, n}(\cdot ; x)\right\|_{L_{q}\left(I_{+}\right)} \leq c n^{-s+1 / q^{\prime}}=: c n^{-\alpha} \tag{3.1}
\end{equation*}
$$

where $c=c(s, r, p, q)$. In the next section we will improve this estimate for the range $2<q \leq \infty$.

Again, we fix $n \geq 1$ and $\beta \geq 1$, to be prescribed, and we let $t_{i}$ be defined by (2.9). Denote

$$
\begin{equation*}
\pi_{s, i}(t ; x):=\pi_{s}\left(t ; x ; t_{i-1}\right), \quad t \in I_{+}, \tag{3.2}
\end{equation*}
$$

where the lefthand side is the Taylor polynomial defined in (2.6), and set

$$
\begin{equation*}
\sigma_{s}(t ; x):=\sigma_{s, n}(t ; x):=\pi_{s, i}(t ; x), \quad t \in I_{i}, \quad i=1, \ldots, n . \tag{3.3}
\end{equation*}
$$

Let $t \in I_{i}, 1 \leq i \leq n-1$. Then integration by parts yields,

$$
\begin{align*}
x(t)-\sigma_{s}(t ; x) & =x(t)-\pi_{s, i}(t ; x) \\
& =\frac{1}{(s-2)!} \int_{t_{i-1}}^{t}\left(x^{(s-1)}(\tau)-x^{(s-1)}\left(t_{i-1}\right)\right)(t-\tau)^{s-2} d \tau \tag{3.4}
\end{align*}
$$

Hence, by the monotonicity of $x^{(s-1)}$, if

$$
\begin{equation*}
\omega_{i}:=x^{(s-1)}\left(t_{i}\right)-x^{(s-1)}\left(t_{i-1}\right), \quad i=1, \ldots, n-1 \tag{3.5}
\end{equation*}
$$

then it is readily seen that

$$
\begin{equation*}
\left\|x(\cdot)-\sigma_{s}(\cdot ; x)\right\|_{L_{q}\left(I_{i}\right)} \leq \frac{\left|I_{i}\right|^{\alpha}}{(s-1)!} \omega_{i}, \quad i=1, \ldots, n-1 \tag{3.6}
\end{equation*}
$$

where $\alpha$ is defined in (3.1).
If $t \in I_{n}$, then

$$
\begin{aligned}
x(t)-\sigma_{s}(t ; x) & =x(t)-\pi_{s, n}(t ; x) \\
& =x(t)-\sum_{k=0}^{r-1} \frac{x^{(k)}\left(t_{n-1}\right)}{k!}\left(t-t_{n-1}\right)^{k}-\sum_{k=r}^{s-1} \frac{x^{(k)}\left(t_{n-1}\right)}{k!}\left(t-t_{n-1}\right)^{k} \\
& \leq x(t)-\sum_{k=0}^{r-1} \frac{x^{(k)}\left(t_{n-1}\right)}{k!}\left(t-t_{n-1}\right)^{k} \\
& =\frac{1}{(r-1)!} \int_{t_{n-1}}^{t} x^{(r)}(\tau)(t-\tau)^{r-1} d \tau
\end{aligned}
$$

where for the inequality we applied that due to (3.6) and the monotonicity of the derivatives, we have $x^{(k)}\left(t_{n-1}\right) \geq 0, k=r, \ldots, s-1$, and the last equality is just integration by parts. By Hölder's inequality we obtain

$$
\begin{equation*}
\left\|x(\cdot)-\sigma_{s}(\cdot ; x)\right\|_{L_{q}\left(I_{n}\right)} \leq\left\|x^{(r)}\right\|_{L_{p}\left(I_{n}\right)} \frac{\left|I_{n}\right|^{r-1 / p+1 / q}}{(r-1)!}=:\left\|x^{(r)}\right\|_{L_{p}\left(I_{n}\right)} \frac{\left|I_{n}\right|^{\rho}}{(r-1)!}, \tag{3.7}
\end{equation*}
$$

which combined with (3.6) yields for $1 \leq q<\infty$,

$$
\begin{aligned}
& \left\|x(\cdot)-\sigma_{s}(\cdot ; x)\right\|_{L_{q}\left(I_{+}\right)}^{q} \\
& \leq \sum_{i=1}^{n-1}\left(\frac{\left|I_{i}\right|^{\alpha}}{(s-1)!} \omega_{i}\right)^{q}+\left(\left\|x^{(r)}\right\|_{L_{p}\left(I_{+}\right)} \frac{\left|I_{n}\right|^{\rho}}{(r-1)!}\right)^{q} \\
& \leq\left(\sum_{i=1}^{n-1} \frac{\left|I_{i}\right|^{\alpha}}{(s-1)!} \omega_{i}+\left\|x^{(r)}\right\|_{L_{p}\left(I_{+}\right)} \frac{\left|I_{n}\right|^{\rho}}{(r-1)!}\right)^{q} .
\end{aligned}
$$

Hence

$$
\begin{align*}
\left\|x(\cdot)-\sigma_{s}(\cdot ; x)\right\|_{L_{q}\left(I_{+}\right)} & \leq c \sum_{i=1}^{n-1}\left|I_{i}\right|^{\alpha} \omega_{i}  \tag{3.8}\\
& +c\left\|x^{(r)}\right\|_{L_{p}\left(I_{+}\right)}\left|I_{n}\right|^{\rho} .
\end{align*}
$$

For $q=\infty$, (3.6) and (3.7) immediately imply (3.8).
We wish to estimate $x^{(r)}(t)$ from below. Let

$$
y(\tau):=\sum_{j=2}^{n} \omega_{j-1}\left(\tau-t_{j-1}\right)_{+}^{0} . \quad \tau \in[0,1]
$$

and denote $m:=s-r-2$. Then by virtue of (2.10) and the monotonicity of $x^{(s-1)}$, we have

$$
\begin{aligned}
& x^{(r)}(t)=c \int_{0}^{t}(t-\tau)^{m} x^{(s-1)}(\tau) d \tau \\
& \geq c \int_{0}^{t}(t-\tau)^{m} y(\tau) d \tau \\
&=c \int_{0}^{t}(t-\tau)^{m} \sum_{j=2}^{n} \omega_{j-1}\left(\tau-t_{j-1}\right)_{+}^{0} d \tau \\
&=c \sum_{j=2}^{n} \omega_{j-1} \int_{t_{j-1}}^{t}(t-\tau)^{m} d \tau \\
&=c^{\prime} \sum_{j=2}^{n} \omega_{j-1}\left(t-t_{j-1}\right)^{m+1} \\
& 9
\end{aligned}
$$

Let $\bar{t}_{i}:=\left(t_{i}+t_{i-1}\right) / 2, i=2, \ldots, n$, and let $t \in\left[\bar{t}_{i}, t_{i}\right)$. Then for $2 \leq j \leq i \leq n$, we have

$$
\begin{aligned}
t-t_{j-1} & =\left(t-\bar{t}_{i}\right)+\left(\bar{t}_{i}-t_{i-1}\right)+\sum_{k=j}^{i-1}\left(t_{k}-t_{k-1}\right) \\
& \geq \frac{1}{2} \sum_{k=j}^{i}\left(t_{k}-t_{k-1}\right)=\frac{1}{2} \sum_{k=j}^{i}\left|I_{k}\right| \\
& \geq \frac{1}{2}(i-j+1)\left|I_{i}\right|
\end{aligned}
$$

since $\left|I_{1}\right| \geq\left|I_{2}\right| \geq \cdots\left|I_{n}\right|$.
Substituting in (3.9), we obtain

$$
x^{(r)}(t) \geq \bar{c} \sum_{j=2}^{i}\left((i-j+1)\left|I_{i}\right|\right)^{m+1} \omega_{j-1}, \quad t \in\left[\bar{t}_{i}, t_{i}\right)
$$

so that for $1 \leq p<\infty$,

$$
\begin{align*}
& \left\|x^{(r)}\right\|_{L_{p}\left(I_{+}\right)}^{p} \\
& \geq \sum_{i=2}^{n}\left|I_{i}\right|\left(\bar{c} \sum_{j=2}^{i}\left((i-j+1)\left|I_{i}\right|\right)^{s-1-r} \omega_{j-1}\right)^{p} \\
& =\sum_{i=1}^{n-1}\left(\bar{c}\left|I_{i+1}\right|^{s-r-1 / p^{\prime}} \sum_{j=1}^{i}(i-j+1)^{s-1-r} \omega_{j}\right)^{p}  \tag{3.10}\\
& =: \sum_{i=1}^{n-1}\left(\bar{c}\left|I_{i+1}\right|^{\gamma} \sum_{j=1}^{i}(i-j+1)^{s-1-r} \omega_{j}\right)^{p}
\end{align*}
$$

where $\bar{c}=2^{-(s-1-r)}((s-1-r)!)^{-1}$.
By virtue of (3.3),

$$
(i-j+1)^{s-1-r} \geq(i-j+1)_{s-r}, \quad 1 \leq j \leq i \leq n-1,
$$

which together with (3.10) implies,

$$
\begin{equation*}
\sum_{i=1}^{n-1}\left(\bar{c}\left|I_{i+1}\right|^{\gamma} \sum_{j=1}^{i}(i-j+1)_{s-r} \omega_{j}\right)^{p} \leq\left\|x^{(r)}\right\|_{L_{p}\left(I_{+}\right)}^{p} \tag{3.11}
\end{equation*}
$$

Given $\beta \geq 1$, straightforward computations show that

$$
c_{1}(n-i)^{\beta-1} n^{-\beta} \leq\left|I_{i}\right| \leq \begin{gather*}
c_{2}(n-i)^{\beta-1} n^{-\beta}  \tag{3.12}\\
10
\end{gather*} \quad i=1, \ldots, n-1,
$$

where $c_{1}=c_{1}(\beta)$ and $c_{2}=c_{2}(\beta)$, and $\left|I_{n}\right|=n^{-\beta}$. In particular, it follows that

$$
\begin{equation*}
\left|I_{i+1}\right| \geq c_{3}\left|I_{i}\right|, \quad i=1, \ldots, n-1 \tag{3.13}
\end{equation*}
$$

for some $c_{3}=c_{3}(\beta)$.
Then, (3.11) becomes

$$
\begin{align*}
& \left(\sum_{i=1}^{n-1}\left(c_{*}(n-i)^{(\beta-1) \gamma} \sum_{j=1}^{i}(i-j+1)_{s-r} \omega_{j}\right)^{p}\right)^{1 / p}  \tag{3.14}\\
& \quad \leq\left\|x^{(r)}\right\|_{L_{p}\left(I_{+}\right)} n^{\beta \gamma}
\end{align*}
$$

and (3.8) becomes

$$
\begin{align*}
\left\|x(\cdot)-\sigma_{s}(\cdot ; x)\right\|_{L_{q}\left(I_{+}\right)} \leq & c^{*} \sum_{i=1}^{n-1} \frac{(n-i)^{(\beta-1) \alpha}}{n^{\beta \alpha}} \omega_{i}  \tag{3.15}\\
& +c^{*}\left\|x^{(r)}\right\|_{L_{p}\left(I_{+}\right)} n^{-\beta \rho}
\end{align*}
$$

where $c^{*}=c^{*}(\beta, r, s, p, q)$ and $c_{*}=c_{*}(\beta, r, s, p, q)$.
We are interested in estimating from above the first sum in (3.15), for all $\omega:=\left(\omega_{1}, \ldots, \omega_{n-1}\right)$, satisfying the constraint (3.14). Therefore we are going to apply Lemma 2 with $m:=s-r$, $M:=\left\|x^{(r)}\right\|_{L_{p}\left(I_{+}\right)} n^{\beta \gamma}$, and the fixed $(n-1)$-tuples $a=\left(a_{1}, \ldots, a_{n-1}\right)$ and $b=\left(b_{1}, \ldots, b_{n-1}\right)$, where

$$
a_{i}:=(n-i)^{(\beta-1) \alpha} n^{-\beta \alpha}, \quad i=1, \ldots, n-1
$$

and

$$
b_{i}:=c_{*}(n-i)^{(\beta-1) \gamma}, \quad i=1, \ldots, n-1 .
$$

To this end, let $\eta>-1$, and $m \geq 1$, and let $\mu \in \mathbb{R}$, be such that $\mu \geq m$. Then it follows by induction (on $m$ ) that,

$$
\begin{aligned}
& \int_{0}^{1} \cdots \int_{0}^{1}\left(\mu-\tau_{1}-\cdots-\tau_{m}\right)^{\eta} d \tau_{1} \cdots d \tau_{m} \\
& =\left(\prod_{k=1}^{m}(\eta+k)\right)^{-1} \sum_{k=0}^{m}(-1)^{k}\binom{m}{k}(\mu-k)^{\eta+m}
\end{aligned}
$$

Hence, for $1 \leq i \leq n-s+r$, we get

$$
\begin{align*}
& \left|\sum_{k=0}^{s-r}(-1)^{k}\binom{s-r}{k}(n-i-k)^{(\beta-1) \alpha}\right| \\
& =\left(\prod_{k=1}^{s-r}((\beta-1) \alpha-k+1)\right)  \tag{3.16}\\
& \quad \times\left|\int_{0}^{1} \cdots \int_{0}^{1}\left(n-i-\tau_{1}-\cdots-\tau_{s-r}\right)^{(\beta-1) \alpha-s+r} d \tau_{1} \cdots d \tau_{s-r}\right| \\
& \leq\left(\prod_{k=1}^{s-r}((\beta-1) \alpha-k+1)\right)(n-i)^{(\beta-1) \alpha-s+r},
\end{align*}
$$

provided we take

$$
\begin{equation*}
\beta \geq 1+(s-r) \alpha^{-1}, \tag{3.17}
\end{equation*}
$$

which is always possible since $\alpha \geq \rho>0$.
For $n-s+r+1 \leq i \leq n-1$, we trivially have

$$
\begin{equation*}
\left|\sum_{k=0}^{s-r}(-1)^{k}\binom{s-r}{k}(n-i-k)_{+}^{(\beta-1) \alpha}\right| \leq 2^{s-r}(s-r)^{(\beta-1) \alpha} \tag{3.18}
\end{equation*}
$$

where $(n-i-k)_{+}:=\max \{n-i-k, 0\}$.
With the $a_{i}$ 's and $b_{i}$ 's above, (3.16) and (3.18) imply

$$
\begin{align*}
& \left|\sum_{k=0}^{s-r}(-1)^{k}\binom{s-r}{k} a_{i+k}\right| b_{i}^{-1} \\
& \leq c n^{-\beta \alpha}  \tag{3.19}\\
& \quad \times \begin{cases}(n-i)^{(\beta-1) \rho-s+r}, & 1 \leq i \leq n-s+r \\
1, & n-s+r+1 \leq i \leq n-1 .\end{cases}
\end{align*}
$$

Let

$$
\begin{equation*}
\beta \geq 1+(s-r) \rho^{-1} \tag{3.20}
\end{equation*}
$$

so that in particular (3.17) holds, and take $1<p<\infty$. Then

$$
\sum_{i=1}^{n-s+r}\left((n-i)^{(\beta-1) \rho-s+r}\right)^{p^{\prime}} \leq n^{((\beta-1) \rho-s+r) p^{\prime}+1}
$$

Hence, by (3.19),

$$
\begin{align*}
& \sum_{i=1}^{n-1}\left(\left|\sum_{k=0}^{s-r}(-1)^{k}\binom{s-r}{k} a_{i+k}\right| b_{i}^{-1}\right)^{p^{\prime}}  \tag{3.21}\\
& \leq c n^{-p^{\prime} \beta \alpha}\left(n^{((\beta-1) \rho-s+r) p^{\prime}+1}+s-r-1\right) .
\end{align*}
$$

Similarly, for $p=1$ it follows from that

$$
\begin{aligned}
& \max _{1 \leq i \leq n-1}\left|\sum_{k=0}^{s-r}(-1)^{k}\binom{s-r}{k} a_{i+k}\right| b_{i}^{-1} \\
& \leq c n^{-\beta \alpha} n^{(\beta-1) \rho-s+r} .
\end{aligned}
$$

Observe that for $1 \leq p<\infty$

$$
n^{-\beta \alpha} n^{(\beta-1) \rho-s+r+1 / p^{\prime}}=n^{-\beta \gamma} n^{-\alpha} .
$$

Thus, if we choose $\beta$ so big that it satisfies (3.20), then (3.21) and Lemma 2 provide an upper bound for the first sum on the righthand side of (3.15). Namely,

$$
\begin{equation*}
\sum_{i=1}^{n-1} \frac{(n-i)^{(\beta-1) \alpha}}{n^{\beta \alpha}} \omega_{i} \leq c\left\|x^{(r)}\right\|_{L_{p}\left(I_{+}\right)} n^{-\alpha} \tag{3.22}
\end{equation*}
$$

Since by virtue of (3.20),

$$
n^{-\beta \rho} \leq n^{-\alpha}
$$

we conclude by (3.22) that for $1 \leq p<\infty$,

$$
\left\|x(\cdot)-\sigma_{s}(\cdot ; x)\right\|_{L_{q}\left(I_{+}\right)} \leq c\left\|x^{(r)}\right\|_{L_{p}\left(I_{+}\right)} n^{-\alpha}=c\left\|x^{(r)}\right\|_{L_{p}\left(I_{+}\right)} n^{-s+1 / q^{\prime}}
$$

where $c=c(\beta, r, s, p, q)$.
The case $p=\infty$ is proved in a similar way, with the obvious modification in (3.10) through (3.14). This completes the proof of (3.1).

As we already alluded to at the end of Section 2, for an arbitrary $x \in \Delta_{+}^{s} W_{p}^{r}$, clearly $\sigma_{s}(\cdot ; x) \in \Sigma_{s, n}$. Also, by our construction, the mapping $A: \operatorname{span}\left(\Delta_{+}^{s} W_{p}^{r}\right) \rightarrow \Sigma_{s, n}$, defined by (3.2) and (3.3), is linear. Thus, it follows that

$$
\begin{equation*}
d_{n}\left(\Delta_{+}^{s} W_{p}^{r}\right)_{L_{q}}^{k o l} \leq d_{n}\left(\Delta_{+}^{s} W_{p}^{r}\right)_{L_{q}}^{l i n} \leq c n^{-s+1 / q^{\prime}}, \quad n \geq s, \quad 1 \leq q \leq \infty \tag{3.23}
\end{equation*}
$$

where $c=c(r, s, p, q)$. This proves the upper bound in (1.1) for $1 \leq q \leq 2$.

## 4. Theorem 1, the uppers bounds: Refined estimates

For $2<q \leq \infty$, we are able to improve the estimates (3.23). We do that in this section, by applying discretization techniques.

In this section $n \geq 1$ may vary, so we are going to keep it as an index in the relevant places. We take $x \in \Delta_{+}^{s} W_{p}^{r}$ satisfying (2.10). Let

$$
w_{n}(t):=w_{\beta, n}(t):=n^{-1}\left(1-|t|+n^{-\beta}\right)^{(\beta-1) / \beta}, \quad t \in I
$$

We first show that

$$
\left\|\left(x(\cdot)-\sigma_{s, n}(\cdot ; x)\right) w_{n}^{-1 / q^{\prime}}(\cdot)\right\|_{L_{1}\left(I_{+}\right)} \leq c n^{-\alpha}, \quad n \geq 1
$$

where $c=c(\beta, r, s, p, q)$, and where $\alpha$ is defined in (3.1) and $\sigma_{s, n}(\cdot ; x)$ is defined in (3.3) (note that it was denoted $\sigma_{s}(\cdot ; x)$ there).

Indeed, it is easy to verify that

$$
c_{1}\left|I_{n, i}\right| \leq w_{n}(t) \leq c_{2}\left|I_{n, i}\right|, \quad t \in I_{n, i}, \quad 1 \leq i \leq n
$$

for some $c_{1}=c_{1}(\beta)$ and $c_{2}=c_{2}(\beta)$.
Let $\omega_{n, i}:=\omega_{i}$, where $\omega_{i}$ is defined by (3.5). Then by virtue of (3.6) with $q=1$, it readily follows that

$$
\begin{aligned}
\left\|\left(x(\cdot)-\sigma_{s, n}(\cdot ; x)\right) w_{n}^{-1 / q^{\prime}}(\cdot)\right\|_{L_{1}\left(I_{n, i}\right)} & \leq c\left|I_{n, i}\right|^{s}\left|I_{n, i}\right|^{-1 / q^{\prime}} \omega_{n, i}=c\left|I_{n, i}\right|^{s-1 / q^{\prime}} \omega_{n, i} \\
& =c\left|I_{n, i}\right|^{\alpha} \omega_{n, i}, \quad i=1, \ldots, n-1,
\end{aligned}
$$

and

$$
\begin{aligned}
\left\|\left(x(\cdot)-\sigma_{s, n}(\cdot ; x)\right) w_{n}^{-1 / q^{\prime}}(\cdot)\right\|_{L_{1}\left(I_{n, n}\right)} & \leq c\left\|x^{(r)}\right\|_{L_{p}\left(I_{+}\right)}\left|I_{n, n}\right|^{r-1 / p+1}\left|I_{n, n}\right|^{-1 / q^{\prime}} \\
& =c\left\|x^{(r)}\right\|_{L_{p}\left(I_{+}\right)}\left|I_{n, n}\right|^{r-1 / p+1 / q} \\
& =c\left\|x^{(r)}\right\|_{L_{p}\left(I_{+}\right)}\left|I_{n, n}\right|^{\rho}
\end{aligned}
$$

where $c=c(\beta, r, s, p, q)$. Hence,

$$
\begin{aligned}
\left\|\left(x(\cdot)-\sigma_{s, n}(\cdot ; x)\right) w_{n}^{-1 / q^{\prime}}(\cdot)\right\|_{L_{1}\left(I_{+}\right)} & \leq c \sum_{i=1}^{n-1}\left|I_{n, i}\right|^{\alpha} \omega_{n, i} \\
& +c\left\|x^{(r)}\right\|_{L_{p}\left(I_{+}\right)}\left|I_{n, n}\right|^{\rho},
\end{aligned}
$$

so that the righthand side is the same as that of (3.8).
Following the explanation at the end of Section 2 and the proof in Section 3, we conclude that with $\beta$ satisfying (3.20), for each $x \in \Delta_{+}^{s} W_{p}^{r}$, there is an appropriate $\sigma_{s, n}(\cdot ; x)$ such that

$$
\begin{equation*}
\left\|\left(x(\cdot)-\sigma_{s, n}(\cdot ; x)\right) w_{n}^{-1 / q^{\prime}}(\cdot)\right\|_{L_{1}(I)} \leq c n^{-\alpha}, \quad n \geq 1 \tag{4.1}
\end{equation*}
$$

where $c=c(\beta, r, s, p, q)$.
Let $\Sigma_{+, s, n}$ be the space of piecewise polynomials $\sigma: I_{+} \mapsto \mathbb{R}$, which are polynomials of degree $\leq s-1$ on the intervals $I_{n, i}, i=1, \ldots, n$, with endpoints $t_{n, i}, i=0, \ldots, n$, defined in (2.9). Then $\operatorname{dim}\left(\Sigma_{+, s, n}\right)=s n$, and $\Sigma_{+, s, n} \subseteq \Sigma_{+, s, 2 n}, n \geq 1$.

Define a one-to-one mapping between the spaces $\Sigma_{+, s, n}$ and $\mathbb{R}^{s n}$ by the linear invertible discretization operators

$$
T_{+, n}: \Sigma_{+, s, n} \ni \sigma_{n} \mapsto \tau=\left(\tau_{1}, \ldots, \tau_{s n}\right) \in \mathbb{R}^{s n}
$$

where

$$
\tau_{i}:=(s n)^{-\beta / q}(s n-i+1)^{(\beta-1) / q} \sigma_{n}\left(t_{s n, i-1}\right), \quad i=1, \ldots, s n .
$$

The inverse mapping is

$$
T_{+, n}^{-1}: \mathbb{R}^{s n} \ni \tau=\left(\tau_{1}, \ldots, \tau_{s n}\right) \mapsto \sigma_{n} \in \Sigma_{+, s, n}
$$

where $\sigma_{n}$ is uniquely defined by the interpolation equations

$$
\sigma_{n}\left(t_{s n, i-1}\right):=(s n)^{\beta / q}(s n-i+1)^{-(\beta-1) / q} \tau_{i}, \quad i=1, \ldots, s n .
$$

We will prove that

$$
\begin{equation*}
c_{1}\left\|T_{+, n} \sigma_{n}\right\|_{l_{q}^{s n}} \leq\left\|\sigma_{n}\right\|_{L_{q}\left(I_{+}\right)} \leq c_{2}\left\|T_{+, n} \sigma_{n}\right\|_{l_{q}^{s n}} \tag{4.2}
\end{equation*}
$$

where $c_{1}=c_{1}(\beta, s, q)$ and $c_{2}=c_{2}(\beta, s, q)$.
To this end, let

$$
\sigma_{n}(t):=p_{n, i}(t), \quad t \in I_{n, i}, \quad i=1, \ldots, n
$$

where $p_{n i}$ are polynomials of degree $\leq s-1$. Then,

$$
\begin{equation*}
\left\|\sigma_{n}\right\|_{L_{q}\left(I_{+}\right)}^{q}=\sum_{i=1}^{n}\left\|p_{n, i}\right\|_{L_{q}\left(I_{n, i}\right)}^{q} \tag{4.3}
\end{equation*}
$$

Clearly, $t_{s n, s(i-1)+j-1} \in I_{n, i}, j=1, \ldots, s$, and

$$
p_{n, i}(t)=\sum_{j=1}^{s} p_{n, i}\left(t_{s n, s(i-1)+j-1}\right) l_{j}\left(t ; I_{n, i}\right), \quad t \in I_{n, i}, \quad i=1, \ldots, n
$$

where

$$
l_{j}\left(t ; I_{n, i}\right):=\prod_{\substack{1 \leq k \leq s \\ k \neq j}} \frac{t-t_{s n, s(i-1)+k-1}}{t_{s n, s(i-1)+j-1}-t_{s n, s(i-1)+k-1}}, \quad t \in I_{n, i}, \quad j=1, \ldots, s
$$

are the Lagrange fundamental polynomials of degree $s-1$ on $I_{n, i}$.

It is readily seen that

$$
\max _{1 \leq j \leq s}\left\|l_{j}\left(\cdot ; I_{n, i}\right)\right\|_{L_{\infty}\left(I_{n, i}\right)} \leq\left(\frac{\left|I_{n, i}\right|}{\left|I_{s n, s i}\right|}\right)^{s-1} \leq c, \quad i=1, \ldots, n
$$

where $c=c(\beta, s)$. Hence

$$
\begin{aligned}
& \left\|p_{n, i}\right\|_{L_{\infty}\left(I_{n, i}\right)} \\
& \leq\left(\sum_{j=1}^{s}\left|p_{n, i}\left(t_{s n, s(i-1)+j-1}\right)\right|\right)\left(\max _{1 \leq j \leq s}\left\|l_{j}\left(\cdot ; I_{n, i}\right)\right\|_{L_{\infty}\left(I_{n, i}\right)}\right) \\
& \leq c s^{1 / q^{\prime}}\left(\sum_{j=1}^{s}\left|p_{n, i}\left(t_{s n, s(i-1)+j-1}\right)\right|^{q}\right)^{1 / q} .
\end{aligned}
$$

This in turn implies that

$$
\begin{aligned}
\left\|p_{n, i}\right\|_{L_{q}\left(I_{n, i}\right)}^{q} & \leq\left|I_{n, i}\right|\left\|p_{n, i}\right\|_{L_{\infty}\left(I_{n, i}\right)}^{q} \\
& \leq c\left|I_{n, i}\right| \sum_{j=1}^{s}\left|p_{n, i}\left(t_{s n, s(i-1)+j-1}\right)\right|^{q} \\
& \leq c \sum_{j=1}^{s}(s n)^{-\beta}(s n-s i+1)^{\beta-1}\left|p_{n, i}\left(t_{s n, s(i-1)+j-1}\right)\right|^{q}
\end{aligned}
$$

where we applied (3.12).
Finally, by (4.3) we conclude that

$$
\begin{aligned}
\left\|\sigma_{n}\right\|_{L_{q}\left(I_{+}\right)}^{q} & =\sum_{i=1}^{n}\left\|p_{n, i}\right\|_{L_{q}\left(I_{n, i}\right)}^{q} \\
& \leq c \sum_{i=1}^{n} \sum_{j=1}^{s}(s n)^{-\beta}(s n-s i+s-j+1)^{\beta-1}\left|p_{n, i}\left(t_{s n, s(i-1)+j-1}\right)\right|^{q} \\
& =c \sum_{i=1}^{s n}(s n)^{-\beta}(s n-i+1)^{\beta-1}\left|\sigma_{n}\left(t_{s n, i-1}\right)\right|^{q} \\
& =c\left\|T_{+, n} \sigma_{n}\right\|_{l_{q}^{s n}}
\end{aligned}
$$

where $c=c(\beta, s, q)$, and the righthand side of (4.2) is proved.
For the lefthand inequality in (4.2), we first observe that for all polynomials $p$ of degree $\leq s-1$ and any interval $J$ we have

$$
\|p\|_{L_{q}(J)} \geq c|J|^{1 / q}\|p\|_{L_{\infty}(J)}
$$

where $c=c(s, q)$. In particular

$$
\begin{equation*}
\left\|p_{n, i}\right\|_{L_{q}\left(I_{n, i}\right)} \geq c\left|I_{n, i}\right|^{1 / q}\left\|p_{n, i}\right\|_{L_{\infty}\left(I_{n, i}\right)}, \quad i=1, \ldots, n \tag{4.4}
\end{equation*}
$$

where $c=c(s, q)$.
Now for $1 \leq i \leq n$,

$$
\begin{aligned}
& \left|I_{n, i}\right|^{1 / q}\left\|p_{n, i}\right\|_{L_{\infty}\left(I_{n, i}\right)} \\
& \geq\left|I_{n, i}\right|^{1 / q} \max _{1 \leq j \leq s}\left|p_{n, i}\left(t_{s n, s(i-1)+j-1}\right)\right| \\
& \geq s^{-1 / q^{\prime}}\left|I_{n, i}\right|^{1 / q}\left(\sum_{j=1}^{s}\left|p_{n, i}\left(t_{s n, s(i-1)+j-1}\right)\right|^{q}\right)^{1 / q} \\
& \geq c\left(\sum_{j=1}^{s}(s n)^{-\beta}(s n-s(i-1)-j+1)^{\beta-1}\left|p_{n, i}\left(t_{s n, s(i-1)+j-1}\right)\right|^{q}\right)^{1 / q},
\end{aligned}
$$

where $c=c(\beta, s, q)$, and where for the last inequality we applied (3.12) and (3.13). Hence, by (4.3) and (4.4),

$$
\begin{aligned}
\left\|\sigma_{n}\right\|_{L_{q}\left(I_{+}\right)}^{q} \geq & \sum_{i=1}^{n}\left\|p_{n, i}\right\|_{L_{q}\left(I_{n, i}\right)}^{q} \\
& \geq c \sum_{i=1}^{n} \sum_{j=1}^{s}(s n)^{-\beta}(s n-s(i-1)-j+1)^{\beta-1}\left|p_{n, i}\left(t_{s n, s(i-1)+j-1}\right)\right|^{q} \\
& =c \sum_{i=1}^{s n}(s n)^{-\beta}(s n-i+1)^{\beta-1}\left|\sigma_{n}\left(t_{s n, i-1}\right)\right|^{q} \\
& =c\left\|T_{+, n} \sigma_{n}\right\|_{l_{q}^{s n}}
\end{aligned}
$$

where $c=c(\beta, s, q)$, and the lefthand side of (4.2) is proved.
Taking into account that

$$
c_{1} w_{2 n}(t) \leq w_{n}(t) \leq c_{2} w_{2 n}(t), \quad t \in I, \quad n \geq 1
$$

where $c_{1}=c_{1}(\beta)$ and $c_{2}=c_{2}(\beta)$, a similar proof (see the proof of (4.1)), yields

$$
\begin{equation*}
c_{1}\left\|T_{+, n} \sigma_{n}\right\|_{l_{1}^{s n}} \leq\left\|\sigma_{n} w_{n}^{-1 / q^{\prime}}\right\|_{L_{1}\left(I_{+}\right)} \leq c_{2}\left\|T_{+, n} \sigma_{n}\right\|_{l_{1}^{n}} \tag{4.5}
\end{equation*}
$$

where $c_{1}=c_{1}(\beta, s, q)$ and $c_{2}=c_{2}(\beta, s, q)$.
Given $x \in \Delta_{+}^{s} W_{p}^{r}$ satisfying (2.10), set

$$
n_{\nu}:=2^{\nu}, \quad \nu \geq 0,
$$

and denote

$$
\delta_{s, n_{\nu}}(t ; x):=\left\{\begin{array}{ll}
\sigma_{s, 1}(t ; x), & \nu=0, \\
\sigma_{s, n_{\nu}}(t ; x)-\sigma_{s, n_{\nu-1}}(t ; x), & \nu \geq 1,
\end{array} \quad t \in I_{+}\right.
$$

so that $\delta_{s, n_{\nu}}(\cdot ; x) \in \Sigma_{+, s, n_{\nu}}, \nu \geq 0$. Moreover, for $\nu \geq 1$, it follows by (3.1) that

$$
\begin{aligned}
\left\|\delta_{s, n_{\nu}}(\cdot ; x) w_{n_{\nu}}^{-1 / q^{\prime}}(\cdot)\right\|_{L_{1}\left(I_{+}\right)} \leq & c\left\|\left(x(\cdot)-\sigma_{s, n_{\nu}}(\cdot ; x)\right) w_{n_{\nu}}^{-1 / q^{\prime}}(\cdot)\right\|_{L_{1}\left(I_{+}\right)} \\
& +c\left\|\left(x(\cdot)-\sigma_{s, n_{\nu-1}}(\cdot ; x)\right) w_{n_{\nu-1}}^{-1 / q^{\prime}}(\cdot)\right\|_{L_{1}\left(I_{+}\right)} \\
\leq & c n_{\nu}^{-\alpha}
\end{aligned}
$$

where $c=c(\beta, r, s, p, q)$.
Hence, by virtue of (4.5), we obtain

$$
\left\|T_{+, n_{\nu}} \delta_{s, n_{\nu}}(\cdot ; x)\right\|_{l_{1}^{s n_{\nu}}} \leq c_{0} n_{\nu}^{-\alpha}, \quad \nu \geq 1
$$

where $c_{0}=c_{0}(\beta, r, s, p, q)$, which in turn implies that for each such function $x$, and every $\nu \geq 1$, the image $T_{+, n_{\nu}} \delta_{s, n_{\nu}}(\cdot ; x)$ belongs to the octahedron

$$
c_{0} n_{\nu}^{-\alpha} b_{1}^{s n_{\nu}}:=\left\{\tau \mid \tau \in l_{1}^{s n_{\nu}},\|\tau\|_{l_{1}^{s n_{\nu}}} \leq c_{0} n_{\nu}^{-\alpha}\right\}
$$

Let $\left\{m_{\nu}\right\}_{\nu \geq 0}$, be a sequence of integers such that $m_{0}=s$ and $m_{\nu} \leq s n_{\nu}, \nu \geq 1$. By the definition of the linear $n$-widths, for arbitrary $c^{0}>1$, there exist subspaces $M^{m_{\nu}} \subseteq \mathbb{R}^{s n_{\nu}}$, $\nu \geq 0$, and linear mappings $A_{m_{\nu}}: \mathbb{R}^{s n_{\nu}} \mapsto M^{m_{\nu}}, \nu \geq 0$, such that $M^{m_{0}}=\mathbb{R}^{s}, A_{m_{0}}$ the identity map on $\mathbb{R}^{s}$,

$$
\operatorname{dim}\left(M^{m_{\nu}}\right) \leq m_{\nu}, \quad \nu \geq 1
$$

and

$$
\sup _{\tau \in b_{1}^{s n_{\nu}}}\left\|\tau-A_{m_{\nu}} \tau\right\|_{l_{q}^{s n_{\nu}}} \leq c^{0} d_{m_{\nu}}\left(b_{1}^{s n_{\nu}}\right)_{l_{q}^{s n_{\nu}}}^{l i n}, \quad \nu \geq 1
$$

Hence,

$$
\begin{equation*}
\left\|\tau-A_{m_{\nu}} \tau\right\|_{l_{q}^{s n_{\nu}}} \leq c^{*} n_{\nu}^{-s+1 / q^{\prime}} d_{m_{\nu}}\left(b_{1}^{s n_{\nu}}\right)_{l_{q}^{s n_{\nu}}}^{l i n}, \quad \tau \in c_{0} n_{\nu}^{-s+1 / q^{\prime}} b_{1}^{s n_{\nu}}, \quad \nu \geq 1 \tag{4.6}
\end{equation*}
$$

where $c^{*}=c_{0} c^{0}$.
Now let

$$
\Sigma_{+, s, n_{\nu}} \supseteq \Sigma_{+, s, n_{\nu}}^{m_{\nu}}:=T_{+, n_{\nu}}^{-1} M^{m_{\nu}}, \quad \nu \geq 0
$$

Then $\operatorname{dim}\left(\sum_{+, s, n_{\nu}}^{m_{\nu}}\right)=\operatorname{dim}\left(M^{m_{\nu}}\right), \nu \geq 0$, and if

$$
\Sigma_{+, s, n_{\mu}}^{m_{0}, \ldots, m_{\mu}}:=\operatorname{span}\left(\bigcup_{\nu=0}^{\mu} \Sigma_{+, s, n_{\nu}}^{m_{\nu}}\right), \quad \mu \geq 0
$$

then $\Sigma_{+, s, n_{\mu}}^{m_{0}, \ldots, m_{\mu}} \subseteq \Sigma_{+, s, n_{\mu}}, \mu \geq 0$, and

$$
\operatorname{dim}\left(\Sigma_{+, s, n_{\mu}}^{m_{0}, \ldots, m_{\mu}}\right) \leq \sum_{\nu=0}^{\mu} m_{\nu}, \quad \mu \geq 0
$$

Define the linear mappings

$$
A_{+}^{m_{\nu}}: \Sigma_{+, s, n_{\nu}} \mapsto \Sigma_{+, s, n_{\nu}}^{m_{\nu}}, \quad \nu \geq 0
$$

by

$$
A_{+}^{m_{\nu}} \sigma_{s, n_{\nu}}:=T_{+, n_{\nu}}^{-1} A_{m_{\nu}} T_{+, n_{\nu}} \sigma_{s, n_{\nu}}, \quad \nu \geq 0
$$

Then each $x \in \Delta_{+}^{s} W_{p}^{r}$ may be expanded on $I_{+}$into

$$
\begin{equation*}
x(t)=\left(x(t)-\sigma_{s, n_{\mu}}(t ; x)\right)+\sum_{\nu=0}^{\mu} \delta_{s, n_{\nu}}(t ; x), \quad \mu \geq 0 \tag{4.7}
\end{equation*}
$$

so we set the linear mappings

$$
A_{+}^{m_{0}, \ldots, m_{\mu}} x(t):=\sum_{\nu=0}^{\mu} A_{+}^{m_{\nu}} \delta_{s, n_{\nu}}(t ; x), \quad t \in I_{+}, \quad \mu \geq 0
$$

and we conclude that $A_{+}^{m_{0}, \ldots, m_{\mu}} x \in \Sigma_{+, s, n_{\mu}}^{m_{0}, \ldots, m_{\mu}}$.
In view of (4.7) we have

$$
\begin{align*}
& \left\|x(\cdot)-A_{+}^{m_{0}, \ldots, m_{\mu}} x(\cdot)\right\|_{L_{q}\left(I_{+}\right)} \\
& \leq\left\|x(\cdot)-\sigma_{s, n_{\mu}}(\cdot ; x)\right\|_{L_{q}\left(I_{+}\right)}  \tag{4.8}\\
& \quad+\sum_{\nu=1}^{\mu}\left\|\delta_{s, n_{\nu}}(\cdot ; x)-T_{+, n_{\nu}}^{-1} A_{m_{\nu}} T_{+, n_{\nu}} \delta_{s, n_{\nu}}(\cdot ; x)\right\|_{L_{q}\left(I_{+}\right)},
\end{align*}
$$

where we observe that if $\nu=0$, then

$$
\delta_{s, 1}(\cdot ; x)-T_{+, 1}^{-1} A_{m_{0}} T_{+, 1} \delta_{s, 1}(\cdot ; x)=0 .
$$

By virtue of (3.1),

$$
\begin{equation*}
\left\|x(\cdot)-\sigma_{s, n_{\mu}}(\cdot ; x)\right\|_{L_{q}\left(I_{+}\right)} \leq c n_{\mu}^{-s+1 / q^{\prime}}, \quad \mu \geq 0 \tag{4.9}
\end{equation*}
$$

where $c=c(\beta, r, s, p, q)$. Further, for $\nu \geq 1$,

$$
\begin{gathered}
T_{+, n_{\nu}}\left(\delta_{s, n_{\nu}}(\cdot ; x)-T_{+, n_{\nu}}^{-1} A_{m_{\nu}} T_{+, n_{\nu}} \delta_{s, n_{\nu}}(\cdot ; x)\right) \\
=T_{+, n_{\nu}} \delta_{s, n_{\nu}}(\cdot ; x)-A_{m_{\nu}} T_{+, n_{\nu}} \delta_{s, n_{\nu}}(\cdot ; x) \\
19
\end{gathered}
$$

Hence, by virtue of (4.2) and (4.6),

$$
\begin{align*}
& \left\|\delta_{s, n_{\nu}}(\cdot ; x)-T_{+, n_{\nu}}^{-1} A_{m_{\nu}} T_{+, n_{\nu}} \delta_{s, n_{\nu}}(\cdot ; x)\right\|_{L_{q}\left(I_{+}\right)} \\
& \leq c_{2}\left\|T_{+, n_{\nu}} \delta_{s, n_{\nu}}(\cdot ; x)-A_{m_{\nu}} T_{+, n_{\nu}} \delta_{s, n_{\nu}}(\cdot ; x)\right\|_{l_{q}^{s n_{\nu}}}  \tag{4.10}\\
& \leq c n_{\nu}^{-\alpha} d_{m_{\nu}}\left(b_{1}^{s n_{\nu}}\right)_{l_{q}^{s n_{\nu}}}^{l i n}
\end{align*}
$$

where $c=c(\beta, r, s, p, q)$. So we substitute (4.9) and (4.10) into (4.8) to obtain

$$
\begin{align*}
\left\|x(\cdot)-A_{+}^{m_{0}, \ldots, m_{\mu}} x(\cdot)\right\|_{L_{q}\left(I_{+}\right)} \leq & c n_{\mu}^{-\alpha} \\
& +c \sum_{\nu=1}^{\mu} n_{\nu}^{-\alpha} d_{m_{\nu}}\left(b_{1}^{s n_{\nu}}\right)_{l_{q}^{s n_{\nu}}}^{l i n} \tag{4.11}
\end{align*}
$$

where $c=c(\beta, r, s, p, q)$.
Let $\mu \geq 1$, and take

$$
m_{\nu}:= \begin{cases}s 2^{\nu}, & \text { if } 0 \leq \nu \leq \mu  \tag{4.12}\\ s 2^{2 \mu-\nu}, & \text { if } \mu<\nu \leq 2 \mu\end{cases}
$$

Since

$$
d_{m_{\nu}}\left(b_{1}^{s n_{\nu}}\right)_{l_{q}^{s n_{\nu}}}^{l i n}=d_{s n_{\nu}}\left(b_{1}^{s n_{\nu}}\right)_{l_{q}^{s n_{\nu}}}^{l i n}=0, \quad \nu=0, \ldots, \mu
$$

it follows by (4.11) that

$$
\begin{align*}
\left\|x(\cdot)-A_{+}^{m_{0}, \ldots, m_{2 \mu}} x(\cdot)\right\|_{L_{q}\left(I_{+}\right)} \leq & c n_{2 \mu}^{-\alpha} \\
& +c \sum_{\nu=\mu+1}^{2 \mu} n_{\nu}^{-\alpha} d_{m_{\nu}}\left(b_{1}^{s n_{\nu}}\right)_{l_{q}^{s n_{\nu}}}^{l i n}, \tag{4.13}
\end{align*}
$$

where $c=c(\beta, r, s, p, q)$.
For $2<q<\infty$, we estimate the widths in (4.13) by [G, Theorem 2], namely,

$$
d_{m_{\nu}}\left(b_{1}^{s n_{\nu}}\right)_{l_{q}^{s n_{\nu}}}^{l i n} \leq \hat{c} n_{\nu}^{1 / q} m_{\nu}^{-1 / 2}, \quad \nu=\mu+1, \ldots, 2 \mu
$$

where $\hat{c}=\hat{c}(s, q)$. Hence, we conclude from (4.12) that

$$
\begin{align*}
\sum_{\nu=\mu+1}^{2 \mu} n_{\nu}^{-\alpha} d_{m_{\nu}}\left(b_{1}^{s n_{\nu}}\right)_{l_{q}^{s n_{\nu}}}^{l i n} & \leq \hat{c} \sum_{\nu=\mu+1}^{2 \mu} 2^{-\alpha \nu}\left(s 2^{\nu}\right)^{1 / q}\left(s 2^{2 \mu-\nu}\right)^{-1 / 2} \\
& =\hat{c} s^{1 / q-1 / 2} 2^{-\mu} \sum_{\nu=\mu+1}^{2 \mu} 2^{-(s-3 / 2) \nu}  \tag{4.14}\\
& \leq \check{c} 2^{-(s-1 / 2) \mu}
\end{align*}
$$

where $\check{c}=\check{c}(s, q)$.
If $q=\infty$, we apply [LGM, Chapter 14, (7.2)], to obtain

$$
d_{m_{\nu}}\left(b_{1}^{s n_{\nu}}\right)_{l_{\infty}^{s n_{\nu}}}^{l i n} \leq c\left(\ln \left(e n_{\nu} / m_{\nu}\right) / m_{\nu}\right)^{1 / 2}, \quad \nu=\mu+1, \ldots, 2 \mu
$$

where $c$ is an absolute constant. Hence, we conclude from (4.12) that

$$
\begin{aligned}
& \sum_{\nu=\mu+1}^{2 \mu} n_{\nu}^{-\alpha} d_{m_{\nu}}\left(b_{1}^{s n_{\nu}}\right)_{l_{\infty}^{s n_{\nu}}}^{l i n} \\
& \leq c \sum_{\nu=\mu+1}^{2 \mu} 2^{-(s-1) \nu}\left(\ln \frac{e s 2^{\nu}}{s 2^{2 \mu-\nu}}\right)^{1 / 2}\left(s 2^{2 \mu-\nu}\right)^{-1 / 2} \\
& =c s^{-1 / 2} 2^{-\mu} \sum_{\nu=\mu+1}^{2 \mu}(1+(2 \nu-2 \mu) \ln 2)^{1 / 2} 2^{-(s-3 / 2) \nu} \\
& \leq c 2^{1 / 2} s^{-1 / 2} 2^{-\mu} \sum_{\nu=\mu+1}^{\infty}(\nu-\mu+1)^{1 / 2} 2^{-(s-3 / 2) \nu} \\
& \leq c 2^{1 / 2} s^{-1 / 2} 2^{-\mu} \int_{\mu+1}^{\infty}(t-\mu+1)^{1 / 2} 2^{-(s-3 / 2) t} d t \\
& =c 2^{s-2} s^{-1 / 2} 2^{-(s-1 / 2) \mu} \int_{2}^{\infty} t^{1 / 2} 2^{-(s-3 / 2) t} d t \\
& =\bar{c} 2^{-(s-1 / 2) \mu},
\end{aligned}
$$

where $\bar{c}=\bar{c}(s)$.
Finally, since $s \geq 2$, we have

$$
2^{-2 \alpha \mu} \leq 2^{-(s-1 / 2) \mu}, \quad n \geq 1, \quad 2<q \leq \infty
$$

Hence, combining (4.13), (4.14) and (4.15), yields

$$
\left\|x(\cdot)-A_{+}^{m_{0}, \ldots, m_{2 \mu}} x(\cdot)\right\|_{L_{q}\left(I_{+}\right)} \leq c 2^{-(s-1 / 2) \mu}, \quad 2<q \leq \infty
$$

where $c=c(\beta, r, s, p, q)$.
For $\mu=0$, it follows by (4.9) that

$$
\left\|x(\cdot)-A_{+}^{m_{0}} x(\cdot)\right\|_{L_{q}\left(I_{+}\right)} \leq c, \quad 2<q \leq \infty
$$

Thus, we conclude that

$$
E\left(\Delta_{+}^{s} W_{p}^{r}, \Sigma_{+, s, n_{2 \mu}}^{m_{0}, \ldots, m_{2 \mu}}\right)_{L_{q}\left(I_{+}\right)}^{l i n} \leq 2_{21}^{c(s-1 / 2) \mu}, \quad \mu \geq 0, \quad 2<q \leq \infty
$$

where $c=c(\beta, r, s, p, q)$, while by (4.12),

$$
\operatorname{dim}\left(\Sigma_{+, s, n_{2 \mu}}^{m_{0}, \ldots, m_{2 \mu}}\right) \leq \sum_{\nu=0}^{2 \mu} m_{\nu}=s\left(2^{\mu+1}+2^{\mu}-2\right)<3 s 2^{\mu}, \quad \mu \geq 0
$$

Similarly, we define the subspaces $\Sigma_{-, s, n_{2 \mu}}^{m_{0}, \ldots, m_{2 \mu}}$ on the interval $I_{-}$, so that

$$
\operatorname{dim}\left(\Sigma_{-, s, n_{2 \mu}}^{m_{0}, \ldots, m_{2 \mu}}\right)<3 s 2^{\mu}, \quad \mu \geq 0
$$

and

$$
E\left(\Delta_{+}^{s} W_{p}^{r}, \Sigma_{-, s, n_{2 \mu}}^{m_{0}, \ldots, m_{2 \mu}}\right)_{L_{q}\left(I_{-}\right)}^{l i n} \leq c 2^{-(s-1 / 2) \mu}, \quad \mu \geq 0, \quad 2<q \leq \infty
$$

where $c=c(\beta, r, s, p, q)$.
Given any $\sigma_{+} \in \Sigma_{+, s, n_{2 \mu}}^{m_{0}, \ldots, m_{2 \mu}}\left(I_{+}\right)$and $\sigma_{-} \in \Sigma_{s, n_{2 \mu}}^{m_{0}, \ldots, m_{2 \mu}}\left(I_{-}\right)$, we glue them together into

$$
\sigma(t):= \begin{cases}\sigma_{+}(t), & t \in(0,1) \\ \left(\sigma_{+}(0)+\sigma_{-}(0)\right) / 2, & t=0, \\ \sigma_{-}(t), & t \in(-1,0)\end{cases}
$$

and we denote the set of all such piecewise polynomials by $\Sigma_{s, n_{2 \mu}}^{m_{0}, \ldots, m_{2 \mu}}$. Then,

$$
\operatorname{dim}\left(\sum_{s, n_{2 \mu}}^{m_{0}, \ldots, m_{2 \mu}}\right) \leq 6 s 2^{\mu}
$$

and

$$
E\left(\Delta_{+}^{s} W_{p}^{r}, \Sigma_{s, n_{2 \mu}}^{m_{0}, \ldots, m_{2 \mu}}\right)_{L_{q}(I)}^{l i n} \leq c 2^{-(s-1 / 2) \mu}, \quad \mu \geq 0, \quad 2<q \leq \infty
$$

where $c=c(\beta, r, s, p, q)$. Therefore, a standard technique yields that

$$
d_{n}\left(\Delta_{+}^{s} W_{p}^{r}\right)_{L_{q}(I)}^{k o l} \leq d_{n}\left(\Delta_{+}^{s} W_{p}^{r}\right)_{L_{q}(I)}^{l i n} \leq c n^{-s+1 / 2}, \quad n \geq s, \quad 2<q \leq \infty
$$

where $c=c(\beta, r, s, p, q)$. This concludes the proof of the improved upper bounds for $2<$ $q \leq \infty$, and completes the proof of the upper bounds in Theorem 1.

## 5. Theorem 2, the uppers bounds

Recall that $s>r+1 \geq 2$. We fix $n \geq 1$, and we use the same notation as in the beginning of Section 2, but we will choose $\beta$ differently.

Given $x \in \Delta_{+}^{s} W_{p}^{r}$ that satisfies (2.10). For $n=1$, we take

$$
\sigma_{s, 1}(t ; x):=0, \quad t \in I
$$

Then by Hölder's inequality we get

$$
\begin{equation*}
\left\|x(\cdot)-\sigma_{s, 1}(\cdot ; x)\right\|_{L_{q}(I)} \leq c\left\|x^{(r)}\right\|_{L_{p}(I)} \tag{5.1}
\end{equation*}
$$

For $n \geq 2$, we denote by $\sigma_{2}\left(\cdot ; x^{(s-2)}\right):=\sigma_{2, n}\left(\cdot ; x^{(s-2)}\right)$, the piecewise linear function, with knots $t_{i}, i=0,1, \ldots, n-2$, which interpolates $x^{(s-2)}$ at $t_{i}, i=0, \pm 1, \ldots, \pm(n-1)$, defined in (2.9). Recalling that $x^{(s-2)}$ is convex in $I$, we conclude that so is $\sigma_{2}$, and that

$$
\begin{equation*}
0 \leq x^{(s-2)}(\tau)-\sigma_{2}\left(\tau ; x^{(s-2)}\right) \leq x^{(s-2)}(\tau)-x^{(s-2)}\left(t_{n-1}\right), \quad t_{n-1} \leq \tau<1 \tag{5.2}
\end{equation*}
$$

Now we set

$$
\sigma_{s}(t ; x):=\sigma_{s, n}(t ; x):=\frac{1}{(s-3)!} \int_{0}^{t} \sigma_{2}\left(\tau ; x^{(s-2)}\right)(t-\tau)^{s-3} d \tau, \quad t \in I_{+}
$$

which, evidently, is $s$-monotone in $I_{+}$. We will estimate the $L_{q}$ distance between $x$ and $\sigma_{s}(\cdot ; x)$ in $I_{+}$. Integration by parts yields,

$$
\begin{aligned}
x(t)-\sigma_{s}(t ; x) & =\frac{1}{(s-3)!} \int_{0}^{t}\left(x^{(s-2)}(\tau)-\sigma_{s}^{(s-2)}(\tau ; x)\right)(t-\tau)^{s-3} d \tau \\
& =\frac{1}{(s-3)!} \int_{0}^{t}\left(x^{(s-2)}(\tau)-\sigma_{2}\left(\tau ; x^{(s-2)}\right)\right)(t-\tau)^{s-3} d \tau
\end{aligned}
$$

so that for $1 \leq q<\infty$,

$$
\begin{align*}
& \left\|x(\cdot)-\sigma_{s}(\cdot ; x)\right\|_{L_{q}\left(I_{+}\right)}^{q} \\
& \leq c(s, q) \int_{0}^{1}\left(\int_{0}^{t}\left|x^{(s-2)}(\tau)-\sigma_{2}\left(\tau ; x^{(s-2)}\right)\right|(t-\tau)^{s-3} d \tau\right)^{q} d t  \tag{5.3}\\
& =c(s, q) \sum_{i=1}^{n} \int_{I_{i}}\left(\int_{0}^{t}\left|x^{(s-2)}(\tau)-\sigma_{2}\left(\tau ; x^{(s-2)}\right)\right|(t-\tau)^{s-3} d \tau\right)^{q} d t
\end{align*}
$$

where $c(s, q):=((s-3)!)^{-q}$.
Let $t \in I_{i}, 1 \leq i \leq n-1$. Then we have

$$
\begin{align*}
& \int_{0}^{t}\left|x^{(s-2)}(\tau)-\sigma_{2}\left(\tau ; x^{(s-2)}\right)\right|(t-\tau)^{s-3} d \tau \\
& \leq \int_{0}^{t_{i}}\left|x^{(s-2)}(\tau)-\sigma_{2}\left(\tau ; x^{(s-2)}\right)\right|\left(t_{i}-\tau\right)^{s-3} d \tau \\
& \leq \sum_{j=1}^{i} \int_{I_{j}}\left|x^{(s-2)}(\tau)-\sigma_{2}\left(\tau ; x^{(s-2)}\right)\right|\left(t_{i}-t_{j-1}\right)^{s-3} d \tau  \tag{5.4}\\
& \leq \sum_{j=1}^{i}\left|I_{j}\right|\left(t_{i}-t_{j-1}\right)^{s-3}\left\|x^{(s-2)}(\cdot)-\sigma_{2}\left(\cdot ; x^{(s-2)}\right)\right\|_{L_{\infty}\left(I_{j}\right)} \\
& =\sum_{j=1}^{i}\left|I_{j}\right|\left(\sum_{k=j}^{i}\left|I_{k}\right|\right)^{s-3}\left\|x^{(s-2)}(\cdot)-\sigma_{2}\left(\cdot ; x^{(s-2)}\right)\right\|_{L_{\infty}\left(I_{j}\right)}
\end{align*}
$$

Since $x^{(s-1)}$ is nondecreasing in $I_{+}$, and $\sigma_{2}$ interpolates $x^{(s-2)}$ at both endpoints of each interval $I_{i}, 1 \leq i \leq n-1$, it follows by Whitney's inequality that

$$
\begin{align*}
\left\|x^{(s-2)}(\cdot)-\sigma_{2}\left(\cdot ; x^{(s-2)}\right)\right\|_{L_{\infty}\left(I_{j}\right)} & \leq \omega_{2}\left(x^{(s-1)} ; I_{j} ;\left|I_{j}\right|\right) \\
& \leq\left|I_{j}\right| \omega\left(x^{(s-1)} ; I_{j} ;\left|I_{j}\right|\right)  \tag{5.5}\\
& =\left|I_{j}\right| \omega_{j}, \quad j=1, \ldots, n-1,
\end{align*}
$$

where $\omega\left(x^{(s-1)} ; I_{j} ; t\right)$ and $\omega_{2}\left(x^{(s-1)} ; I_{j} ; t\right)$ are, respectively, the first and second moduli of smoothness of $x^{(s-1)}$, in $I_{j}$, and $\omega_{j}$ was defined in (3.5).

For $t \in I_{n}$, we similarly obtain,

$$
\begin{aligned}
& \int_{0}^{t}\left|x^{(s-2)}(\tau)-\sigma_{2}\left(\tau ; x^{(s-2)}\right)\right|(t-\tau)^{s-3} d \tau \\
& =\int_{0}^{t_{n-1}}\left|x^{(s-2)}(\tau)-\sigma_{2}\left(\tau ; x^{(s-2)}\right)\right|(t-\tau)^{s-3} d \tau \\
& \quad+\int_{t_{n-1}}^{t}\left|x^{(s-2)}(\tau)-\sigma_{2}\left(\tau ; x^{(s-2)}\right)\right|(t-\tau)^{s-3} d \tau \\
& \leq \sum_{j=1}^{n-1}\left|I_{j}\right|\left(\sum_{k=j}^{n-1}\left|I_{k}\right|\right)^{s-3}\left\|x^{(s-2)}(\cdot)-\sigma_{2}\left(\cdot ; x^{(s-2)}\right)\right\|_{L_{\infty}\left(I_{j}\right)} \\
& \quad+\int_{t_{n-1}}^{t}\left|x^{(s-2)}(\tau)-\sigma_{2}\left(\tau ; x^{(s-2)}\right)\right|(t-\tau)^{s-3} d \tau
\end{aligned}
$$

and by virtue of (5.2), integration by parts yields,

$$
\begin{align*}
& \frac{1}{(s-3)!} \int_{t_{n-1}}^{t}\left|x^{(s-2)}(\tau)-\sigma_{2}\left(\tau ; x^{(s-2)}\right)\right|(t-\tau)^{s-3} d \tau \\
& \leq \frac{1}{(s-3)!} \int_{t_{n-1}}^{t}\left(x^{(s-2)}(\tau)-x^{(s-2)}\left(t_{n-1}\right)\right)(t-\tau)^{s-3} d \tau \\
& =x(t)-\sum_{k=0}^{s-2} \frac{x^{(k)}\left(t_{n-1}\right)}{k!}\left(t-t_{n-1}\right)^{k}  \tag{5.7}\\
& \leq x(t)-\sum_{k=0}^{r-1} \frac{x^{(k)}\left(t_{n-1}\right)}{k!}\left(t-t_{n-1}\right)^{k} \\
& =\frac{1}{(r-1)!} \int_{t_{n-1}}^{t} x^{(r)}(\tau)(t-\tau)^{r-1} d \tau \\
& \leq \frac{1}{(r-1)!}\left\|x^{(r)}\right\|_{L_{p}\left(I_{+}\right)}\left|I_{n}\right|^{r-1 / p}
\end{align*}
$$

where for the second inequality we used the fact that $x^{(k)}\left(t_{n-1}\right) \geq 0, r-1<k \leq s-2$, and for the last inequality we applied Hölder's inequality.

We substitute (5.4) through (5.7) in (5.3), and use $(|a|+|b|)^{q} \leq 2^{q-1}\left(|a|^{q}+|b|^{q}\right)$, to obtain

$$
\begin{align*}
& \left\|x(\cdot)-\sigma_{s}(\cdot ; x)\right\|_{L_{q}\left(I_{+}\right)}^{q} \\
& \leq  \tag{5.8}\\
& \qquad\left(\sum_{i=1}^{n-1}\left(\left|I_{i}\right|^{1 / q} \sum_{j=1}^{i}\left|I_{j}\right|^{2}\left(\sum_{k=j}^{i}\left|I_{k}\right|\right)^{s-3} \omega_{j}\right)^{q}\right. \\
& \left.\quad+\left\|x^{(r)}\right\|_{L_{p}\left(I_{+}\right)}^{q}\left|I_{n}\right|^{q \rho}\right)
\end{align*}
$$

for some $c=c(s, q)$. Since $\left|I_{1}\right| \geq \cdots \geq\left|I_{n}\right|$, we have

$$
\begin{aligned}
& \sum_{i=1}^{n-1}\left(\left|I_{i}\right|^{1 / q} \sum_{j=1}^{i}\left|I_{j}\right|^{2}\left(\sum_{k=j}^{i}\left|I_{k}\right|\right)^{s-3} \omega_{j}\right)^{q} \\
& \leq \sum_{i=1}^{n-1}\left(\sum_{j=1}^{i}\left|I_{j}\right|^{2+1 / q}\left(\sum_{k=j}^{i}\left|I_{k}\right|\right)^{s-3} \omega_{j}\right)^{q} \\
& \leq \sum_{i=1}^{n-1}\left(\sum_{j=1}^{n-1}\left|I_{j}\right|^{2+1 / q}\left(\sum_{k=j}^{n}\left|I_{k}\right|\right)^{s-3} \omega_{j}\right)^{q} \\
& =(n-1)\left(\sum_{i=1}^{n-1}\left|I_{i}\right|^{2+1 / q}\left(\sum_{j=i}^{n}\left|I_{j}\right|\right)^{s-3} \omega_{i}\right)^{q} .
\end{aligned}
$$

Hence, (5.8) becomes,

$$
\begin{align*}
& \left\|x(\cdot)-\sigma_{s}(\cdot ; x)\right\|_{L_{q}\left(I_{+}\right)} \\
& \leq  \tag{5.9}\\
& \quad c(n-1)^{1 / q} \sum_{i=1}^{n-1}\left|I_{i}\right|^{2+1 / q}\left(\sum_{j=i}^{n}\left|I_{j}\right|\right)^{s-3} \omega_{i} \\
& \quad+c\left\|x^{(r)}\right\|_{L_{p}\left(I_{+}\right)}\left|I_{n}\right|^{\rho}
\end{align*}
$$

where $c=c(s, q)$. It is easy to verify that (5.9) is also valid for $q=\infty$.
We now proceed as in Section 2. Applying (3.12), and

$$
\sum_{j=i}^{n}\left|I_{j}\right|=t_{n}-t_{i-1}=n^{-\beta}(n-i+1)^{\beta}, \quad i=1, \ldots, n,
$$

it follows from (5.9) that

$$
\begin{align*}
\left\|x(\cdot)-\sigma_{s}(\cdot ; x)\right\|_{L_{q}\left(I_{+}\right)} \leq & c \sum_{i=1}^{n-1} \frac{(n-i)^{\beta \alpha-2-1 / q}}{n^{\beta \alpha-1 / q}} \omega_{i}  \tag{5.10}\\
& +c\left\|x^{(r)}\right\|_{L_{p}\left(I_{+}\right)} n^{-\beta \rho}
\end{align*}
$$

and we have to estimate the first sum on the righthand side, for all $\omega:=\left(\omega_{1}, \ldots, \omega_{n-1}\right)$, satisfying the constraint (3.14) (and the analogous one for $p=\infty$ ). Again, we apply Lemma 2 with $m:=s-r, M:=\left\|x^{(r)}\right\|_{L_{p}\left(I_{+}\right)} n^{\beta \gamma}$, where $\gamma$ was defined in (3.10), and the fixed ( $n-1$ )-tuples $a=\left(a_{1}, \ldots, a_{n-1}\right)$ and $b=\left(b_{1}, \ldots, b_{n-1}\right)$, where

$$
a_{i}:=(n-i)^{\beta \alpha-2-1 / q} n^{-\beta \alpha-1 / q}, \quad i=1, \ldots, n-1,
$$

and

$$
b_{i}:=c_{*}(n-i)^{(\beta-1) \gamma}, \quad i=1, \ldots, n-1 .
$$

Just as in (3.16) we obtain for $1 \leq i \leq n-s+r$,

$$
\begin{align*}
& \left|\sum_{k=0}^{s-r}(-1)^{k}\binom{s-r}{k}(n-i-k)^{\beta \alpha-2-1 / q}\right| \\
& \leq\left(\prod_{k=1}^{s-r}(\beta \alpha-2-1 / q-k+1)\right)(n-i)^{\beta \alpha-2-1 / q-s+r}, \tag{5.11}
\end{align*}
$$

provided

$$
\begin{equation*}
\beta \geq(s-r+2+1 / q) \alpha^{-1} . \tag{5.12}
\end{equation*}
$$

Also, for $n-s+r+1 \leq i \leq n-1$, we trivially have

$$
\left|\sum_{k=0}^{s-r}(-1)^{k}\binom{s-r}{k}(n-i-k)_{+}^{\beta \alpha-2-1 / q}\right| \leq 2^{s-r}(s-r)^{\beta \alpha-2-1 / q}
$$

where $(n-i-k)_{+}:=\max \{n-i-k, 0\}$.
Therefore, combining with (5.11), we conclude that for every $1 \leq i \leq n-1$,

$$
\begin{align*}
& \left|\sum_{k=0}^{s-r}(-1)^{k}\binom{s-r}{k} a_{i+k}\right| b_{i}^{-1}  \tag{5.13}\\
& \leq c n^{-\beta \alpha+1 / q}(n-i)^{\beta \rho-2-1 / p^{\prime}-1 / q} .
\end{align*}
$$

Let $1<p \leq \infty$. Then for

$$
\begin{gather*}
\beta \geq\left(2+1 / p^{\prime}+1 / q\right) \rho^{-1}  \tag{5.14}\\
\left(\sum_{i=1}^{n-1}\left((n-i)^{\beta \rho-2-1 / p^{\prime}-1 / q}\right)^{p^{\prime}}\right)^{1 / p^{\prime}} \leq c n^{\beta \rho-2-1 / q}, \tag{5.15}
\end{gather*}
$$

and similarly for $p=1$,

$$
\begin{equation*}
\max _{1 \leq i \leq n-1}(n-i)^{\beta \rho-2-1 / p^{\prime}-1 / q} \leq c n^{\beta \rho-2-1 / q} \tag{5.16}
\end{equation*}
$$

Observing that for $1 \leq p \leq \infty$,

$$
n^{-\beta \alpha+1 / q} n^{\beta \rho-2-1 / q} n^{\beta \gamma}=n^{-2}
$$

we choose $\beta$ so big that it satisfies both (5.12) and (5.14), then Lemma 2, (5.13) and (5.15), and (5.16), provide an upper bound for the first sum on the righthand side of (5.10). Namely,

$$
\begin{equation*}
\sum_{i=1}^{n-1} \frac{(n-i)^{\beta \alpha-2-1 / q}}{n^{\beta \alpha-1 / q}} \omega_{i} \leq c\left\|x^{(r)}\right\|_{L_{p}\left(I_{+}\right)} n^{-2} \tag{5.17}
\end{equation*}
$$

Finally, for $\beta$ satisfying (5.14),

$$
\begin{equation*}
n^{-\beta \rho} \leq n^{-2} \tag{5.18}
\end{equation*}
$$

Thus, substituting (5.17) and (5.18) into the righthand side of (5.10), we obtain

$$
\left\|x(\cdot)-\sigma_{s}(\cdot ; x)\right\|_{L_{q}\left(I_{+}\right)} \leq c\left\|x^{(r)}\right\|_{L_{p}\left(I_{+}\right)} n^{-2}
$$

where $c=c(\beta, r, s, p, q)$.
As explained in Section 2, for an arbitrary $x \in \Delta_{+}^{s} W_{p}^{r}$ we obtain an appropriate $\sigma_{s, n}(\cdot ; x)$ which is clearly in $\Delta_{+}^{s} \Sigma_{s, n}$. Thus, it follows that

$$
d_{n}\left(\Delta_{+}^{s} W_{p}^{r}, \Delta_{+}^{s} L_{q}\right)_{L_{q}}^{k o l} \leq c n^{-2}, \quad n \geq s
$$

where $c=c(r, s, p, q)$. This completes our proof of the upper bounds in (1.2).

## 6. The lower bounds

We begin with
Proof of Theorem 1. If for $l \geq 1$, we denote

$$
\stackrel{\circ}{W_{p}^{l}}:\left\{x \mid x \in W_{p}^{l}, x^{(k)}(0)=0, k=0, \ldots, l-1\right\}
$$

then, evidently,

$$
\begin{equation*}
\Delta_{+}^{s} W_{p}^{s-1}=\Delta_{+}^{s} \stackrel{\circ}{W}_{p}^{s-1}+\Pi_{s-1}, \tag{6.1}
\end{equation*}
$$

where $\Pi_{s-1}$ is the space of polynomials of degree $<s-1$.

It clearly follows by (6.1) that

$$
\begin{equation*}
d_{n+s-1}\left(\Delta_{+}^{s} W_{p}^{s-1}\right)_{L_{q}}^{k o l} \leq d_{n}\left(\Delta_{+}^{s} \stackrel{\circ}{W}_{p}^{s-1}\right)_{L_{q}}^{k o l}, \quad n \geq s \tag{6.2}
\end{equation*}
$$

For $x \in \stackrel{\circ}{W}_{p}^{s-1}$, integration by parts yields,

$$
x^{(r)}(t)=\frac{1}{(s-r-2)!} \int_{0}^{t} x^{(s-1)}(\tau)(t-\tau)^{s-r-2} d \tau, \quad t \in I,
$$

so that by Hölder's inequality, $\left\|x^{(r)}\right\|_{L_{p}} \leq c_{*}\left\|x^{(s-1)}\right\|_{L_{p}}$, where $c_{*}=2^{1 / p}((s-r-2)!)^{-1}$. Hence

$$
\stackrel{\circ}{W}_{p}^{s-1} \subseteq c_{*} \stackrel{\circ}{W}_{p}^{r},
$$

which implies

$$
\begin{equation*}
c_{*}^{-1} \Delta_{+}^{s} \stackrel{\circ}{W_{p}^{s-1}} \subset \Delta_{+}^{s} \stackrel{\circ}{W_{p}^{r}} \subset \Delta_{+}^{s} W_{p}^{r} \tag{6.3}
\end{equation*}
$$

Thus, by virtue of (6.2)

$$
d_{n}\left(\Delta_{+}^{s} W_{p}^{r}\right)_{L_{q}}^{k o l} \geq c_{*}^{-1} d_{n+s-1}\left(\Delta_{+}^{s} W_{p}^{s-1}\right)_{L_{q}}^{k o l}, \quad n \geq s
$$

Now, our lower bound in (1.1), follows immediately by Theorem A. This completes the proof of the lower bounds in (1.1), and altogether concludes the proof of Theorem 1.

Proof of Theorem 2. Again by (6.1) we have

$$
d_{n+s-1}\left(\Delta_{+}^{s} W_{p}^{s-1}, \Delta_{+}^{s} L_{q}\right)_{L_{q}}^{k o l} \leq d_{n}\left(\Delta_{+}^{s} \stackrel{\circ}{W_{p}^{s-1}}, \Delta_{+}^{s} L_{q}\right)_{L_{q}}^{k o l}, \quad n \geq s
$$

which combined with (6.3) yields

$$
d_{n}\left(\Delta_{+}^{s} W_{p}^{r}, \Delta_{+}^{s} L_{q}\right)_{L_{q}}^{k o l} \geq c_{*}^{-1} d_{n+s}\left(\Delta_{+}^{s} W_{p}^{s-1}, \Delta_{+}^{s} L_{q}\right)_{L_{q}}^{k o l}, \quad n \geq s
$$

Now, our lower bound in (1.2), follows immediately by Theorem D. This completes the proof.

## Acknowledgment

The authors thank the referee for helpful comments and suggestions that improved and shortened some of the proofs.
