In this paper, we solve a function field analogue of classical problems in analytic number theory, concerning the autocorrelations of divisor functions, in the limit of a large finite field.

## 1. Introduction

The goal of this paper is to study a function field analogue of classical problems in analytic number theory, concerning the autocorrelations of divisor functions. First, we review the problems over the integers  $\mathbb{Z}$  and then we proceed to investigate the same problems over the rational function field  $\mathbb{F}_q(t)$ .

### (a) The additive divisor problem over $\mathbb{Z}$

Let  $d_k(n)$  be the number of representations of  $n$  as a product of  $k$  positive integers ( $d_2$  is the standard divisor function). Several authors have studied the *additive divisor problem* (other names are 'shifted divisor' and 'shifted convolution'), which is to get bounds, or asymptotics, for the sum

$$D_k(x; h) := \sum_{n \leq x} d_k(n) d_k(n + h), \quad (1.1)$$

where  $h \neq 0$  is fixed for this discussion.

The case  $k = 2$  (the ordinary divisor function) has a long history: Ingham [1] computed the leading term, and Estermann [2] gave an asymptotic expansion

$$\begin{aligned} & \sum_{n \leq x} d_2(n) d_2(n + h) \\ &= x P_2(\log x; h) + O(x^{11/12} (\log x)^3), \end{aligned} \quad (1.2)$$

where

$$P_2(u; h) = \frac{1}{\zeta(2)} \sigma_{-1}(h) u^2 + a_1(h) u + a_2(h) \quad (1.3)$$

with

$$\sigma_w(h) = \sum_{d|h} d^w \quad (1.4)$$

and  $a_1(h)$  and  $a_2(h)$  are very complicated coefficients.

The size of the remainder term has great importance in applications for various problems in analytic number theory, in particular, the dependence on  $h$ . See Deshouillers & Iwaniec [3] and Heath-Brown [4] for an improvement of the remainder term.

The higher divisor problem  $k \geq 3$  is also of importance, in particular, in relation to computing the moments of the Riemann  $\zeta$ -function on the critical line [5,6]. It is conjectured that

$$D_k(x; h) \sim x P_{2(k-1)}(\log x; h) \quad \text{as } x \rightarrow \infty, \quad (1.5)$$

where  $P_{2(k-1)}(u; h)$  is a polynomial in  $u$  of degree  $2(k-1)$ , whose coefficients depend on  $h$  (and  $k$ ). We can get good upper bounds on the additive divisor problem from results in sieve theory on sums of multiplicative functions evaluated at polynomials, for instance, such as those by Nair & Tenenbaum [7]. The conclusion is that for  $h \neq 0$

$$\sum_{n \leq X} d_k(n) d_k(n+h) \ll X (\log X)^{2(k-1)}, \quad (1.6)$$

and we believe this is the right order of magnitude. But even a conjectural description of the polynomials  $P_{2(k-1)}(u; h)$  is difficult to obtain (see §7, [5,6]).

A variant of the problem about the autocorrelation of the divisor function is to determine an asymptotic for the more general sum given by

$$D_{k,r}(x; h) := \sum_{n \leq x} d_k(n) d_r(n+h). \quad (1.7)$$

Asymptotics are known for the case  $(k, r) = (k, 2)$  for any positive integer  $k \geq 2$ : Linnik [8] showed

$$\begin{aligned} D_{k,2}(x; 1) &= \sum_{n \leq x} d_k(n) d_2(n+1) \\ &= \frac{1}{(k-1)!} \prod_p \left( 1 - \frac{1}{p} + \frac{1}{p} \left( 1 - \frac{1}{p} \right)^{k-1} \right) x (\log x)^k + O(x (\log x)^{k-1} (\log \log x)^{k^4}). \end{aligned} \quad (1.8)$$

Motohashi [9–11] gave an asymptotic expansion

$$D_{k,2}(x; h) = x \sum_{j=0}^k f_{k,j}(h) (\log x)^j + O(x (\log x)^{\varepsilon-1}), \quad (1.9)$$

for all  $\varepsilon > 0$ , where the coefficients  $f_{k,j}(h)$  can in principle be explicitly computed. For an improvement in the  $O$  term, see Fouvry & Tenenbaum [12].

## (b) The Titchmarsh divisor problem over $\mathbb{Z}$

A different problem involving the mean value of the divisor function is the *Titchmarsh divisor problem*. The problem is to understand the average behaviour of the number of divisors of a shifted

prime, that is, the asymptotics of the sum over primes

$$\sum_{p \leq x} d_2(p+a), \quad (1.10)$$

where  $a \neq 0$  is a fixed integer, and  $x \rightarrow \infty$ . Assuming the generalized Riemann hypothesis (GRH), Titchmarsh [13] showed that

$$\sum_{p \leq x} d_2(p+a) \sim C_1 x \quad (1.11)$$

with

$$C_1 = \frac{\zeta(2)\zeta(3)}{\zeta(6)} \prod_{p|a} \left(1 - \frac{p}{p^2 - p + 1}\right), \quad (1.12)$$

and this was proved unconditionally by Linnik [8].

Fouvry [14] and Bombieri *et al.* [15] gave a secondary term,

$$\sum_{p \leq x} d_2(p+a) = C_1 x + C_2 \text{Li}(x) + O\left(\frac{x}{(\log x)^A}\right), \quad (1.13)$$

for all  $A > 1$  and

$$C_2 = C_1 \left( \gamma - \sum_p \frac{\log p}{p^2 - p + 1} + \sum_{p|a} \frac{p^2 \log p}{(p-1)(p^2 - p + 1)} \right), \quad (1.14)$$

with  $\gamma$  being the Euler–Mascheroni constant and  $\text{Li}(x)$  the logarithmic integral function.

In the following sections, we study the additive divisor problem and the Titchmarsh divisor problem over  $\mathbb{F}_q[t]$ , obtaining definitive analogues of the conjectures described above.

### (c) The additive divisor problem over $\mathbb{F}_q[t]$

We denote by  $\mathcal{M}_n$  the set of monic polynomials in  $\mathbb{F}_q[t]$  of degree  $n$ . Note that  $\#\mathcal{M}_n = q^n$ .

The divisor function  $d_k(f)$  is the number of ways to write a monic polynomial  $f$  as a product of  $k$  monic polynomials:

$$d_k(f) = \#\{(a_1, \dots, a_k), f = a_1 \cdot a_2 \cdots a_k\}, \quad (1.15)$$

where it is allowed to have  $a_i = 1$ .

The mean value of  $d_k(f)$  has an exact formula (see lemma 2.2):

$$\frac{1}{q^n} \sum_{f \in \mathcal{M}_n} d_k(f) = \binom{n+k-1}{k-1}. \quad (1.16)$$

Note that  $\binom{n+k-1}{k-1}$  is a polynomial in  $n$  of degree  $k-1$  and leading coefficient  $1/(k-1)!$ . Our first goal is to study the autocorrelation of  $d_k$  in the limit  $q \rightarrow \infty$ . We show:

**Theorem 1.1.** Fix  $n > 1$ . Then

$$\frac{1}{q^n} \sum_{f \in \mathcal{M}_n} d_k(f) d_k(f+h) = \binom{n+k-1}{k-1^2} + O(q^{-1/2}), \quad (1.17)$$

uniformly for all  $0 \neq h \in \mathbb{F}_q[t]$  of degree  $\deg(h) < n$ , as  $q \rightarrow \infty$ .

In light of (1.16), theorem 1.1 may be interpreted as the statement that  $d_k(f)$  and  $d_k(f+h)$  become independent in the limit  $q \rightarrow \infty$  as long as  $\deg(h) < n$ .

To compare with conjecture (1.5) over  $\mathbb{Z}$ , we note that  $\binom{n+k-1}{k-1}^2$  is a polynomial in  $n$  of degree  $2(k-1)$  with leading coefficient  $1/[(k-1)!]^2$ , in agreement with the conjecture (see §7b).

The case  $h = 0$ : As an aside, we note that the case  $h = 0$  is of course dramatically different. Indeed one can show that

$$\lim_{q \rightarrow \infty} \frac{1}{q^n} \sum_{f \in \mathcal{M}_n} d_k(f)^2 = \binom{n+k^2-1}{k^2-1} \quad (1.18)$$

is a polynomial of degree  $k^2 - 1$  in  $n$ , rather than degree  $2(k - 1)$  for non-zero shifts.

Our method in fact gives the more general result:

**Theorem 1.2.** Let  $\mathbf{k} = (k_1, \dots, k_s)$  be a tuple of positive integers and  $\mathbf{h} = (h_1, \dots, h_s)$  a tuple of distinct polynomials in  $\mathbb{F}_q[t]$ . We let

$$D_{\mathbf{k}}(n; \mathbf{h}) = \sum_{f \in \mathcal{M}_n} d_{k_1}(f + h_1) \cdots d_{k_s}(f + h_s).$$

Then, for fixed  $n > 1$ ,

$$\frac{1}{q^n} D_{\mathbf{k}}(n; \mathbf{h}) = \prod_{i=1}^s \binom{n+k_i-1}{k_i-1} + O(q^{-1/2}),$$

uniformly on all tuples  $\mathbf{h} = (h_1, h_2, \dots, h_s)$  of distinct polynomials in  $\mathbb{F}_q[t]$  of degrees  $\deg(h_i) < n$  as  $q \rightarrow \infty$ .

In particular, for  $\mathbf{k} = (2, k)$  we get

$$\begin{aligned} \lim_{q \rightarrow \infty} \frac{1}{q^n} D_{2,k}(n; h) &= (n+1) \binom{n+k-1}{k-1} \\ &= \frac{1}{(k-1)!} \left( n^k + \frac{k^2-k+2}{2} n^{k-1} + \cdots \right), \end{aligned} \quad (1.19)$$

in agreement with (1.8).

### (d) The Titchmarsh divisor problem over $\mathbb{F}_q[t]$

Let  $\mathcal{P}_n$  be the set of monic irreducible polynomials in  $\mathbb{F}_q[t]$  of degree  $n$ . By the Prime Polynomial Theorem, we have

$$\pi_q(n) := \#\mathcal{P}_n = \frac{q^n}{n} + O\left(\frac{q^{n/2}}{n}\right).$$

Our next result is a solution of the Titchmarsh divisor problem over  $\mathbb{F}_q[t]$  in the limit of large finite field.

**Theorem 1.3.** Fix  $n > 1$ . Then

$$\frac{1}{\pi_q(n)} \sum_{P \in \mathcal{P}_n} d_k(P + \alpha) = \binom{n+k-1}{k-1} + O(q^{-1/2}), \quad (1.20)$$

uniformly over all  $0 \neq \alpha \in \mathbb{F}_q[t]$  of degree  $\deg(\alpha) < n$ .

For the standard divisor function ( $k = 2$ ), we find

$$\sum_{P \in \mathcal{P}_n} d_2(P + \alpha) = q^n + \frac{q^n}{n} + O(q^{n-1/2}), \quad (1.21)$$

which is analogous to (1.13) under the correspondence  $x \leftrightarrow q^n$  and  $\log x \leftrightarrow n$ .

### (e) Independence of cycle structure of shifted polynomials

We conclude the introduction with a discussion on the connection between shifted polynomials and random permutations and state a result that lies behind the results stated above.

The cycle structure of a permutation  $\sigma$  of  $n$  letters is the partition  $\lambda(\sigma) = (\lambda_1, \dots, \lambda_n)$  of  $n$  if, in the decomposition of  $\sigma$  as a product of disjoint cycles, there are  $\lambda_j$  cycles of length  $j$ . Note that  $\lambda(\sigma)$  is a partition of  $n$  in the sense that  $\lambda_j \geq 0$  and  $\sum_j j\lambda_j = n$ . For example,  $\lambda_1$  is the number of fixed points of  $\sigma$  and  $\lambda_n = 1$  if and only if  $\sigma$  is an  $n$ -cycle.

For each partition  $\lambda \vdash n$ , the probability that a random permutation on  $n$  letters has cycle structure  $\sigma$  is given by Cauchy's formula [16, ch. 1]:

$$p(\lambda) = \frac{\#\{\sigma \in S_n : \lambda(\sigma) = \lambda\}}{\#S_n} = \prod_{j=1}^n \frac{1}{j^{\lambda_j} \cdot \lambda_j!}. \quad (1.22)$$

For  $f \in \mathbb{F}_q[t]$  of positive degree  $n$ , we say its cycle structure is  $\lambda(f) = (\lambda_1, \dots, \lambda_n)$  if, in the prime decomposition  $f = \prod_j P_j$  (we allow repetition), we have  $\#\{i : \deg(P_i) = j\} = \lambda_j$ . Thus, we get a partition of  $n$ . In analogy with permutation,  $\lambda_1(f)$  is the number of roots of  $f$  in  $\mathbb{F}_q$  (with multiplicity) and  $f$  is irreducible if and only if  $\lambda_n(f) = 1$ .

For a partition  $\lambda \vdash n$ , we let  $\chi_\lambda$  be the characteristic function of  $f \in \mathcal{M}_n$  of cycle structure  $\lambda$ :

$$\chi_\lambda(f) = \begin{cases} 1, & \lambda(f) = \lambda \\ 0, & \text{otherwise.} \end{cases} \quad (1.23)$$

The Prime Polynomial Theorem gives the mean values of  $\chi_\lambda$ :

$$\frac{1}{q^n} \sum_{f \in \mathcal{M}_n} \chi_\lambda(f) = p(\lambda) + O(q^{-1}), \quad (1.24)$$

as  $q \rightarrow \infty$  (see lemma 2.1). We prove independence of cycle structure of shifted polynomials:

**Theorem 1.4.** *For fixed positive integers  $n$  and  $s$  we have*

$$\frac{1}{q^n} \sum_{f \in \mathcal{M}_n} \chi_{\lambda_1}(f + h_1) \cdots \chi_{\lambda_s}(f + h_s) = p(\lambda_1) \cdots p(\lambda_s) + O(q^{-1/2}),$$

uniformly for all  $h_1, \dots, h_s$  distinct polynomials in  $\mathbb{F}_q[t]$  of degrees  $\deg(h_i) < n$  and on all partitions  $\lambda_1, \dots, \lambda_s \vdash n$  as  $q \rightarrow \infty$ .

**Remark.** In this theorem,  $\lambda_1, \dots, \lambda_s$  are partitions of  $n$  and are not the same as the  $\lambda_1, \dots, \lambda_n$  that appear in the definition of  $\lambda(f)$  or  $\lambda(\sigma)$  where in that case the  $\lambda_i$  are the number of parts of length  $i$ .

We note that the statistic of theorem 1.4 is induced from the statistics of the cycle structure of tuples of elements in the direct product  $S_n^s$  of  $s$  copies of the symmetric group on  $n$  letters  $S_n$ . This plays a role in the proof, where we use that a certain Galois group is  $S_n^s$  [17], and we derive the statistic from an explicit Chebotarev theorem. Since we have not found the exact formulation that we need in the literature, we provide a proof in the appendix.

## 2. Mean values

For the reader's convenience, we prove in this section some results for which we did not find a good reference. We define the *norm* of a non-zero polynomial  $f \in \mathbb{F}_q[t]$  to be  $|f| = q^{\deg(f)}$  and set  $|0| = 0$ .

We start by proving (1.24):

**Lemma 2.1.** *If  $\lambda \vdash n$  is a partition of  $n$  and  $n$  is a fixed number then*

$$\frac{1}{q^n} \#\{f \in \mathcal{M}_n : \lambda(f) = \lambda\} = p(\lambda)(1 + O(q^{-1})), \quad (2.1)$$

as  $q \rightarrow \infty$ .

*Proof.* To see this, note that to get a monic polynomial with cycle structure  $\lambda$ , we pick any  $\lambda_1$  primes of degree 1,  $\lambda_2$  primes of degree 2 (irrespective of the choice of ordering), and multiply them together. Thus

$$\#\{f \in \mathcal{M}_n : \lambda(f) = \lambda\} = \prod_{j=1}^n \frac{\pi_A(j)^{\lambda_j}}{\lambda_j!} \left(1 + O\left(\frac{1}{q}\right)\right), \quad (2.2)$$

where  $\pi_A(j)$  is the number of primes of degree  $j$  in  $A = \mathbb{F}_q[t]$ . By the Prime Polynomial Theorem,  $\pi_A(j) = q^j/j + O(q^{j/2}/j)$  whenever  $j \geq 2$  and  $\pi_A(1) = q$ . Hence  $\pi_A(j) = q^j/j + O(q^{j-1}/j)$ . So

$$\begin{aligned} \#\{f \in \mathcal{M}_n : \lambda(f) = \lambda\} &= \prod_{j=1}^n \frac{1}{\lambda_j!} \left(\frac{q^j}{j} + O\left(\frac{q^{j-1}}{j}\right)\right)^{\lambda_j} \\ &= q^{\sum j\lambda_j} \prod_{j=1}^n \frac{1}{j^{\lambda_j} \cdot \lambda_j!} (1 + O(q^{-1})), \end{aligned} \quad (2.3)$$

which by (1.22) gives (2.1). ■

Next, we prove (1.16):

**Lemma 2.2.** *The mean value of  $d_k(f)$  is*

$$\frac{1}{q^n} \sum_{f \in \mathcal{M}_n} d_k(f) = \binom{n+k-1}{k-1}. \quad (2.4)$$

*Proof.* The generating function for  $d_k(f)$  is the  $k$ th power of the zeta function associated to the polynomial ring  $\mathbb{F}_q[t]$ :

$$Z(u)^k = \sum_{f \text{ monic}} d_k(f) u^{\deg f} = \sum_{n=0}^{\infty} \sum_{f \in \mathcal{M}_n} d_k(f) u^n. \quad (2.5)$$

Here,

$$Z(u) = \sum_{f \text{ monic}} u^{\deg f} = \sum_{n=0}^{\infty} q^n u^n = \frac{1}{1-qu}. \quad (2.6)$$

Using the Taylor expansion

$$\frac{1}{(1-x)^k} = \sum_{n=0}^{\infty} \binom{n+k-1}{k-1} x^n \quad (2.7)$$

and comparing the coefficients of  $u^n$  in (2.5) gives

$$q^n \binom{n+k-1}{k-1} = \sum_{f \in \mathcal{M}_n} d_k(f), \quad (2.8)$$

as needed. ■

### 3. Proof of theorem 1.4

In the course of the proof, we shall use the following explicit Chebotarev theorem, which is a special case of theorem A.4 of appendix A:

**Theorem 3.1.** *Let  $A = (A_1, \dots, A_n)$  be an  $n$ -tuple of variables over  $\mathbb{F}_q$ , let  $\mathcal{F}(t) \in \mathbb{F}_q[A][t]$  be monic, separable and of degree  $m$  viewed as a polynomial in  $t$ , let  $L$  be a splitting field of  $\mathcal{F}$  over  $K = \mathbb{F}_q(A)$ , and let  $G = \text{Gal}(\mathcal{F}, K) = \text{Gal}(L/K)$ . Assume that  $\mathbb{F}_q$  is algebraically closed in  $L$ . Then there exists a constant  $c = c(n, \text{tot.deg}(\mathcal{F}))$  such that for every conjugacy class  $C \subseteq G$  we have*

$$\left| \#\{a \in \mathbb{F}_q^n : \text{Fr}_a = C\} - \frac{|C|}{|G|} q^n \right| \leq c q^{n-1/2}.$$

Here  $\text{Fr}_a$  denotes the Frobenius conjugacy class  $((S/R)/\phi)$  in  $G$  associated to the homomorphism  $\phi: R \rightarrow \mathbb{F}_q$  given by  $A \mapsto a \in \mathbb{F}_q^n$ , where  $R = \mathbb{F}_q[A, \text{disc}\mathcal{F}^{-1}]$  and  $S$  is the integral closure of  $R$  in the splitting field of  $\mathcal{F}$ . See appendix A, in particular (A 11), for more details.

Let  $A = (A_1, \dots, A_n)$  be an  $n$ -tuple of variables and set

$$\mathcal{F}_i = T^n + A_1 T^{n-1} + \dots + A_n + h_i(T) \quad \text{and} \quad \mathcal{F} = \mathcal{F}_1 \dots \mathcal{F}_s, \quad (3.1)$$

where the  $h_i$  are distinct polynomials. Let  $L$  be the splitting field of  $\mathcal{F}$  over  $K = \mathbb{F}_q(A)$  and let  $\mathbb{F}$  be an algebraic closure of  $\mathbb{F}_q$ . By [17, Proposition 3.1],

$$G := \text{Gal}(\mathcal{F}, K) = \text{Gal}\left(\frac{L}{\mathbb{F}_q}\right) = \text{Gal}\left(\frac{\mathbb{F}L}{\mathbb{F}\mathbb{F}_q}\right) = S_n^s.$$

In [17], it is assumed that  $q$  is odd, but using [18] that restriction can now be removed for  $n > 2$ . This, in particular, implies that  $L \cap \mathbb{F} = \mathbb{F}_q$  (since the image of the restriction map  $\text{Gal}(\mathbb{F}L/\mathbb{F}\mathbb{F}_q) \rightarrow \text{Gal}(L/K)$  is  $\text{Gal}(L/L \cap \mathbb{F}\mathbb{F}_q)$ , so by the above and Galois correspondence,  $L \cap (\mathbb{F}\mathbb{F}_q) = K$ , and in particular  $L \cap \mathbb{F} = K \cap \mathbb{F} = \mathbb{F}_q$ ). Hence, we may apply theorem 3.1 with the conjugacy class

$$C = \{(\sigma_1, \dots, \sigma_s) \in G : \lambda_{\sigma_i} = \lambda_i\}$$

to get that

$$\left| \#\{a \in \mathbb{F}_q^n : \text{Fr}_a = C\} - |C|/|G| \cdot q^n \right| \leq c(s, n)q^{n-1/2}.$$

Since  $|C|/|G| = p(\lambda_1) \dots p(\lambda_s)$  and since  $\#\{a \in \mathbb{F}_q^n : \text{disc}_T(\mathcal{F})(a) = 0\} = O_{s,n}(q^{n-1})$ , it remains to show that for  $a \in \mathbb{F}_q^n$  with  $\text{disc}_T(\mathcal{F})(a) \neq 0$  we have  $\text{Fr}_a = C$  if and only if  $\lambda_{\mathcal{F}_i(a, T)} = \lambda_i$  for all  $i = 1, \dots, s$ .

And indeed, extend the specialization  $A \mapsto a$  to a homomorphism  $\Phi$  of  $\mathbb{F}_q[A, Y]$  to  $\mathbb{F}$ , where  $Y = (Y_{ij})$ , and  $Y_{i1}, \dots, Y_{in}$  are the roots of  $\mathcal{F}_i$ . Then  $\text{Fr}_a$  is, by definition, the conjugacy class of the Frobenius element  $\text{Fr}_\Phi \in G$ , which is defined by

$$\Phi(\text{Fr}_\Phi(Y_{ij})) = \Phi(Y_{ij})^q. \quad (3.2)$$

Note that  $\text{Fr}_\Phi$  permutes the roots of each  $\mathcal{F}_i$  and hence can be identified with an  $s$ -tuple of permutations  $\text{Fr}_\Phi = (\sigma_1, \dots, \sigma_s) \in G = S_n^s$ . Since the  $\Phi(Y_{ij})$  are distinct, the cycle structure of  $\sigma_i$  equals the cycle structure of the  $\Phi(Y_{ij}) \rightarrow \Phi(Y_{ij})^q$ ,  $j = 1, \dots, n$  by (3.2), which in turn equals the cycle structure of the polynomial  $\mathcal{F}_i(a, T)$ . Hence  $\text{Fr}_\Phi \in C$  if and only if  $\lambda_{\mathcal{F}_i(a, T)} = \lambda_i$  for all  $i$ , as needed. ■

## 4. Proof of theorem 1.1

First, we need the following lemma:

**Lemma 4.1.** *Let  $f \in \mathcal{M}_n$  and  $h \in \mathbb{F}_q[t]$  such that  $\deg(h) < n$ . Then we have that*

$$\#\{f \in \mathcal{M}_n : f \text{ and } f+h \text{ are square-free}\} = q^n + O(q^{n-1}). \quad (4.1)$$

*Proof.* The number of square-free  $f \in \mathcal{M}_n$  is  $q^n - q^{n-1}$  for  $n \geq 2$  (for  $n = 1$  it is  $q$ ), and since  $n > \deg(h)$ , as  $f$  runs over all monic polynomials of degree  $n$  so does  $f+h$ , and hence the number of  $f \in \mathcal{M}_n$  such that  $f+h$  is square-free is also  $q^n - q^{n-1}$ . Therefore, there are at most  $2q^{n-1}$  monic  $f \in \mathcal{M}_n$  for which at least one of  $f$  and  $f+h$  is not square-free, as claimed. ■

We denote by  $\langle A \rangle$  the mean value of an arithmetic function  $A$  over  $\mathcal{M}_n$ :

$$\langle A \rangle := \frac{1}{q^n} \sum_{f \in \mathcal{M}_n} A(f). \quad (4.2)$$

For this, it follows that if  $A$  is an arithmetic function on  $\mathcal{M}_n$  that is bounded independently of  $q$ , then

$$\langle A \rangle = \frac{1}{q^n} \sum_{\substack{f \in \mathcal{M}_n \\ f \text{ and } f+h \text{ square-free}}} A(f) + O(q^{n-1}). \quad (4.3)$$

Now for square-free  $f$ , the divisor function  $d_k(f)$  depends only on the cycle structure of  $f$ , namely

$$d_k(f) = k^{|\lambda(f)|}, \quad (4.4)$$

where for a partition  $\lambda = (\lambda_1, \dots, \lambda_n)$  of  $n$ , we denote by  $|\lambda| = \sum \lambda_j$  the number of parts of  $\lambda$ . Therefore, we may apply (4.3) with (4.4) to get

$$\langle d_k(\bullet) d_k(\bullet + h) \rangle = \langle k^{|\lambda(\bullet)|} k^{|\lambda(\bullet+h)|} \rangle + O(q^{-1}). \quad (4.5)$$

Since the function  $k^{|\lambda(f)|}$  depends only on the cycle structure of  $f$ , it follows from theorem 1.4 that

$$\langle k^{|\lambda(\bullet)|} k^{|\lambda(\bullet+h)|} \rangle = \langle k^{|\lambda(\bullet)|} \rangle \langle k^{|\lambda(\bullet+h)|} \rangle + O(q^{-1/2}) = \langle k^{|\lambda(\bullet)|} \rangle^2 + O(q^{-1/2}). \quad (4.6)$$

Applying again (4.3) with (4.4) together with lemma 2.2, we conclude that

$$\langle k^{|\lambda(\bullet)|} \rangle = \langle d_k(\bullet) \rangle + O(q^{-1}) = \binom{n+k-1}{k-1} + O(q^{-1}). \quad (4.7)$$

Combining (4.5), (4.6) and (4.7) then gives the desired result. ■

## 5. Proof of theorem 1.2

We argue as in §4:

$$\begin{aligned} \left\langle \prod_{i=1}^s d_{k_i}(\bullet + h_i) \right\rangle &= \left\langle \prod_{i=1}^s k_i^{|\lambda(\bullet+h_i)|} \right\rangle + O(q^{-1}) \\ &= \prod_{i=1}^s \langle k_i^{|\lambda(\bullet)|} \rangle + O(q^{-1/2}) \\ &= \prod_{i=1}^s \binom{n+k_i-1}{k_i-1} + O(q^{-1/2}). \end{aligned}$$

(Here the first passage uses (4.3) with (4.4), the last also uses lemma 2.2, and the middle passage is done by invoking theorem 1.4.) ■

## 6. Proof of theorem 1.3

Let  $\mathbf{1}_{\mathcal{P}}$  be the characteristic function of the primes of degree  $n$ , i.e.

$$\mathbf{1}_{\mathcal{P}}(f) = \chi_{(0,0,\dots,0,1)}(f) = \begin{cases} 1, & \text{if } f \in \mathcal{P}_n, \\ 0, & \text{otherwise.} \end{cases} \quad (6.1)$$

The Prime Polynomial Theorem gives that  $\langle \mathbf{1}_{\mathcal{P}} \rangle = 1/n + O(q^{-1})$  and we have calculated in §4 that  $\langle k^{|\lambda(\bullet)|} \rangle = \binom{n+k-1}{k-1} + O(q^{-1})$ . Since these two functions clearly depend only on cycle structures (recall that  $\alpha \neq 0$ ), theorem 1.4 gives

$$\langle \mathbf{1}_{\mathcal{P}}(\bullet) \cdot k^{|\lambda(\bullet)|} \rangle = \langle \mathbf{1}_{\mathcal{P}}(\bullet) \rangle \langle k^{|\lambda(\bullet)|} \rangle = \frac{1}{n} \binom{n+k-1}{k-1} + O(q^{-1/2}). \quad (6.2)$$

Therefore,

$$\begin{aligned} \frac{n}{q^n} \sum_{P \in \mathcal{P}_n} d_k(P + \alpha) &= n \langle \mathbf{1}_{\mathcal{P}}(\bullet) \cdot k^{|\lambda(\bullet)|} \rangle \\ &= \binom{n+k-1}{k-1} + O(q^{-1/2}), \end{aligned}$$

as needed. ■

## 7. Comparing conjectures and our results

In this section, we check the compatibility of the theorems presented in §1c with the known results over the integers.

### (a) Estermann's theorem for $\mathbb{F}_q[t]$

First, we prove the function field analogue of Estermann's result (1.2). For simplicity, we carry it out for  $h = 1$ .

**Theorem 7.1.** *Assume that  $n \geq 1$ . Then*

$$\frac{1}{q^n} \sum_{f \in \mathcal{M}_n} d_2(f) d_2(f+1) = (n+1)^2 - \frac{1}{q} (n-1)^2. \quad (7.1)$$

(Note that  $q$  is fixed in this theorem).

We need two auxiliary lemmas before proving theorem 7.1.

Let  $A, B \in \mathbb{F}_q[t]$  be monic polynomials. We want to count the number of monic polynomial solutions  $(u, v) \in \mathbb{F}_q[t]^2$  of the linear Diophantine equation

$$Au - Bv = 1, \quad \deg(Au) = n = \deg(Bv). \quad (7.2)$$

As follows from the Euclidean algorithm, a necessary and sufficient condition for the equation  $Au - Bv = 1$  to be solvable in  $\mathbb{F}_q[t]$  is  $\gcd(A, B) = 1$ .

**Lemma 7.2.** *Given monic polynomials  $A, B \in \mathbb{F}_q[t]$ ,  $\gcd(A, B) = 1$  and*

$$n \geq \deg(A) + \deg(B), \quad (7.3)$$

*then the set of monic solutions  $(u, v)$  of (7.2) forms a non-empty affine subspace of dimension  $n - \deg(A) - \deg(B)$ , hence the number of solutions is exactly  $q^n / |A||B|$ .*

*Proof.* We first ignore the degree condition. By the theory of the linear Diophantine equation, given a particular solution  $(u_0, v_0) \in \mathbb{F}_q[t]^2$ , all other solutions in  $\mathbb{F}_q[t]^2$  are of the form

$$(u_0, v_0) + k(B, A), \quad (7.4)$$

where  $k \in \mathbb{F}_q[t]$  runs over all polynomials.

Given  $u_0$ , we may replace it by  $u_1 = u_0 + kB$  where  $\deg(u_1) < \deg(B)$  (or is zero), so that we may assume that the particular solution satisfies

$$\deg(u_0) < \deg(B). \quad (7.5)$$

In that case, if  $k \neq 0$  then

$$\deg(u_0 + kB) = \deg(kB) \quad (7.6)$$

and  $u_0 + kB$  is monic if and only if  $k$  is monic. Hence if  $k \neq 0$ , then

$$\begin{aligned} \deg(u_0 + kB) = n - \deg(A) &\Leftrightarrow \deg(kB) = n - \deg(A) \\ &\Leftrightarrow \deg(k) = n - \deg(A) - \deg(B). \end{aligned} \quad (7.7)$$

Thus, the set of solutions of (7.2) is in one-to-one correspondence with the space  $\mathcal{M}_{n-\deg(A)-\deg(B)}$  of monic  $k$  of degree  $n - \deg(A) - \deg(B)$ . In particular, the number of solutions is  $q^n / |A||B|$ . ■

Let

$$S(\alpha, \beta; \gamma, \delta) := \#\{x \in \mathcal{M}_\alpha, y \in \mathcal{M}_\beta, z \in \mathcal{M}_\gamma, u \in \mathcal{M}_\delta : xy - zu = 1\}. \quad (7.8)$$

Then we have the following lemma.

**Lemma 7.3.** For  $\alpha + \beta = n = \gamma + \delta$ ,

$$S(\alpha, \beta; \gamma, \delta) = q^n \times \begin{cases} 1, & \text{if } \min(\alpha, \beta; \gamma, \delta) = 0, \\ 1 - \frac{1}{q}, & \text{otherwise.} \end{cases} \quad (7.9)$$

*Proof.* We have some obvious symmetries from the definition

$$S(\alpha, \beta; \gamma, \delta) = S(\beta, \alpha; \gamma, \delta) = S(\alpha, \beta; \delta, \gamma), \quad (7.10)$$

and hence to evaluate  $S(\alpha, \beta; \gamma, \delta)$  it suffices to assume

$$\alpha \leq \beta, \quad \gamma \leq \delta. \quad (7.11)$$

Assuming (7.11), we write

$$S(\alpha, \beta; \gamma, \delta) = \sum_{\substack{x \in \mathcal{M}_\alpha \\ z \in \mathcal{M}_\gamma \\ \gcd(x,z)=1}} \#\{y \in \mathcal{M}_\beta, u \in \mathcal{M}_\delta : xy - zu = 1\}. \quad (7.12)$$

Note that  $\alpha, \gamma \leq n/2$  (since  $\alpha + \beta = n$  and  $\alpha \leq \beta$ ) and hence  $\alpha + \gamma \leq \frac{1}{2}(\alpha + \beta + \gamma + \delta) = n$ . Thus, we may use lemma 7.2 to deduce that

$$\#\{y \in \mathcal{M}_\beta, u \in \mathcal{M}_\delta : xy - zu = 1\} = q^{n-\alpha-\gamma} \quad (7.13)$$

and therefore

$$S(\alpha, \beta; \gamma, \delta) = q^{n-\alpha-\gamma} \sum_{\substack{x \in \mathcal{M}_\alpha \\ z \in \mathcal{M}_\gamma \\ \gcd(x,z)=1}} 1. \quad (7.14)$$

Recall the Möbius inversion formula, which says that, for monic  $f$ ,  $\sum_{d|f} \mu(d)$  equals 1 if  $f = 1$ , and 0 otherwise. Hence, we may write the coprimality condition  $\gcd(x, z) = 1$  using the Möbius function as

$$\sum_{d|x, d|z} \mu(d) = \begin{cases} 1, & \gcd(x, z) = 1, \\ 0, & \text{otherwise,} \end{cases} \quad (7.15)$$

and therefore

$$\begin{aligned}
 S(\alpha, \beta; \gamma, \delta) &= q^{n-\alpha-\gamma} \sum_{\substack{x \in \mathcal{M}_\alpha \\ z \in \mathcal{M}_\gamma}} \sum_{d|x, d|z} \mu(d) \\
 &= q^{n-\alpha-\gamma} \sum_{\substack{\deg(d) \leq \min(\alpha, \gamma) \\ d \text{ monic}}} \mu(d) \#\{x \in \mathcal{M}_\alpha : d|x\} \cdot \#\{z \in \mathcal{M}_\gamma : d|z\} \\
 &= q^{n-\alpha-\gamma} \sum_{\substack{\deg(d) \leq \min(\alpha, \gamma) \\ d \text{ monic}}} \mu(d) \frac{q^\alpha}{|d|} \cdot \frac{q^\gamma}{|d|} \\
 &= q^n \sum_{\substack{\deg(d) \leq \min(\alpha, \gamma) \\ d \text{ monic}}} \frac{\mu(d)}{|d|^2} \\
 &= q^n \sum_{\substack{\deg(d) \leq \min(\alpha, \beta; \gamma, \delta) \\ d \text{ monic}}} \frac{\mu(d)}{|d|^2}, \tag{7.16}
 \end{aligned}$$

where we have used the fact that  $\alpha \leq \beta$  and  $\gamma \leq \delta$ .

We next claim that

$$\sum_{\substack{\deg(d) \leq \eta \\ d \text{ monic}}} \frac{\mu(d)}{|d|^2} = \begin{cases} 1, & \eta = 0, \\ 1 - \frac{1}{q}, & \eta \geq 1, \end{cases} \tag{7.17}$$

which when we insert into (7.16) proves the lemma.

To prove (7.17), we sum over  $d$  of fixed degree

$$\sum_{\substack{\deg(d) \leq \eta \\ d \text{ monic}}} \frac{\mu(d)}{|d|^2} = \sum_{0 \leq \xi \leq \eta} \frac{1}{q^{2\xi}} \sum_{d \in \mathcal{M}_\xi} \mu(d) \tag{7.18}$$

and recall that [19, ch. 2, exercise 12]

$$\sum_{d \in \mathcal{M}_\xi} \mu(d) = \begin{cases} 1, & \xi = 0, \\ -q, & \xi = 1, \\ 0, & \xi \geq 2, \end{cases} \tag{7.19}$$

from which (7.17) follows. ■

*Proof of theorem 7.1.* We write

$$\begin{aligned}
 v &:= \sum_{f \in \mathcal{M}_n} d_2(f) d_2(f+1) \\
 &= \#\{x, y, z, u \in \mathbb{F}_q[t] \text{ monic} : xy - zu = 1, \deg(xy) = n = \deg(zu)\}. \tag{7.20}
 \end{aligned}$$

We partition this into a sum over variables with fixed degree, that is

$$v = \sum_{\substack{\alpha+\beta=n \\ \gamma+\delta=n \\ \alpha, \beta, \gamma, \delta \geq 0}} S(\alpha, \beta; \gamma, \delta). \tag{7.21}$$

We now input the results of lemma 7.3 into (7.21) to deduce that

$$v = \sum_{\substack{\alpha+\beta=n \\ \gamma+\delta=n \\ \alpha, \beta, \gamma, \delta \geq 0}} q^n \times \begin{cases} 1, & \min(\alpha, \beta; \gamma, \delta) = 0, \\ 1 - \frac{1}{q}, & \text{otherwise.} \end{cases} \tag{7.22}$$

Of the  $(n+1)^2$  quadruples of non-negative integers  $(\alpha, \beta; \gamma, \delta)$  so that  $\alpha + \beta = n = \gamma + \delta$ , there are exactly  $4n$  tuples  $(\alpha, \beta; \gamma, \delta)$  for which  $\min(\alpha, \beta) = 0 = \min(\gamma, \delta)$ , namely they are

$$(n, 0; n, 0), \quad (n, 0; 0, n), \quad (0, n; n, 0) \quad \text{and} \quad (0, n; 0, n) \quad (7.23)$$

and the  $4(n-1)$  tuples of the form

$$(n, 0; i, n-i), \quad (0, n; i, n-i), \quad (i, n-i; n, 0) \quad \text{and} \quad (i, n-i; 0, n) \quad (7.24)$$

for  $0 < i < n$ .

Concluding, we have

$$\begin{aligned} v &= (4 + 4(n-1)) \cdot q^n + [(n+1)^2 - (4 + 4(n-1))] \cdot q^n \left(1 - \frac{1}{q}\right) \\ &= q^n \left( (n+1)^2 - \frac{1}{q}(n-1)^2 \right), \end{aligned} \quad (7.25)$$

proving the theorem. ■

It is easy to check that theorem 1.1 is compatible with the function field analogue of Estermann's result. Taking  $q \rightarrow \infty$  in (7.1), we recover the same results as presented in (1.17) with  $k=2$ .

## (b) Higher divisor functions

Next, we want to check compatibility of our result in theorem 1.1 with what is conjectured over the integers. It is conjectured that

$$D_k(x; h) \sim x P_{2(k-1)}(\log x; h) \quad \text{as } x \rightarrow \infty, \quad (7.26)$$

where  $P_{2(k-1)}(u; h)$  is a polynomial in  $u$  of degree  $2(k-1)$ , whose coefficients depend on  $h$  (and  $k$ ). This conjecture appears in the work of Ivić [20] and Conrey & Gonek [5], and from their work, with some effort, we can explicitly write the conjectural leading coefficient for the desired polynomial. The conjecture over  $\mathbb{Z}$  states that

$$P_{2(k-1)}(u; h) = \frac{1}{[(k-1)!]^2} A_k(h) u^{2k-2} + \dots, \quad (7.27)$$

where

$$A_k(h) = \sum_{m=1}^{\infty} \frac{c_m(h)}{m^2} C_{-k}^2(m) \quad (7.28)$$

with

$$C_{-k}(m) = m^{1-k} \sum_{a_1=1}^m \dots \sum_{a_k=1}^m e\left(\frac{ha_1 \dots a_k}{m}\right), \quad (7.29)$$

where  $e(x) = e^{2\pi i x}$  and  $c_m(h)$  is the Ramanujan sum,

$$c_m(h) = \sum_{\substack{a=1 \\ (a,m)=1}}^m e^{2\pi i(a/m)h} = \sum_{d|\gcd(m,h)} d \mu\left(\frac{m}{d}\right). \quad (7.30)$$

We now translate the conjecture above to the function field setting using the correspondence  $x \leftrightarrow q^n$  and  $\log x \leftrightarrow n$  and that summing over positive integers correspond to summing over monic polynomials in  $\mathbb{F}_q[t]$ . Under this correspondence, the function field analogue of the above polynomial is given in the following conjecture.

**Conjecture 7.4.** For  $q$  fixed, let  $0 \neq h \in \mathbb{F}_q[t]$ . Then as  $n \rightarrow \infty$ ,

$$\sum_{f \in \mathcal{M}_n} d_k(f) d_k(f+h) \sim \frac{1}{[(k-1)!]^2} A_{k,q}(h) q^n n^{2k-2}, \quad (7.31)$$

where

$$A_{k,q}(h) = \sum_{\substack{m \in \mathbb{F}_q[t] \\ \text{monic}}} \frac{c_{m,q}(h) (\gcd(m, h))^{2(k-1)}}{|m|^{2(k-1)}} g_{k-1}^2 \left( \frac{m}{\gcd(m, h)} \right), \quad (7.32)$$

where  $|m| = q^{\deg(m)}$ ,

$$g_{k-1}(f) = \#\{a_1, \dots, a_{k-1} \bmod f : a_1 \dots a_{k-1} \equiv 0 \bmod f\} \quad (7.33)$$

and

$$c_{m,q}(h) = \sum_{d | \gcd(m, h)} |d| \mu \left( \frac{m}{d} \right) \quad (7.34)$$

is the Ramanujan sum over  $\mathbb{F}_q[t]$ . The sum above is over all monic polynomials  $d \in \mathbb{F}_q[t]$ ,  $\mu(f)$  is the Möbius function for  $\mathbb{F}_q[t]$  and  $\Phi(m)$  is the  $\mathbb{F}_q[t]$  analogue for Euler's totient function.

**Remark 7.5.** Note that

$$C_{q,-k}^2(m) = \frac{\gcd(m, h)^{2k-1}}{|m|^{k-1}} g_{k-1}^2 \left( \frac{m}{\gcd(m, h)} \right) \quad (7.35)$$

corresponds to  $C_{-k}^2(m)$  as given in (7.29).

**Remark 7.6.** Note that we establish this conjecture for  $k=2$  and  $h=1$  in theorem 7.1.

We now check that our theorem 1.1 is consistent with the conjecture (7.27) and (7.32) for the leading term of the polynomial  $P_{2(k-1)}(u; h)$ .

The polynomial given by theorem 1.1 is

$$\binom{n+k-1}{k-1} = \frac{1}{[(k-1)!]^2} n^{2(k-1)} + \dots \quad (7.36)$$

We wish to show that, as  $q \rightarrow \infty$ ,  $A_{k,q}(h)/[(k-1)!]^2$  matches the leading coefficient of  $\binom{n+k-1}{k-1}^2$ , that is

$$\lim_{q \rightarrow \infty} A_{k,q}(h) = 1. \quad (7.37)$$

Indeed, from (7.34) we note that  $|c_{m,q}(h)| = O_h(1)$ , and it is easy to see that

$$g_{k-1}(n) \leq n^{k-1} d(n)^{k-1} \ll |n|^{k-2+\epsilon}, \quad \forall \epsilon > 0. \quad (7.38)$$

Thus, we find

$$A_{k,q}(h) = 1 + O \left( \sum_{\substack{m \in \mathcal{M} \\ \deg(m) > 0}} \frac{1}{|m|^{2-\epsilon}} \right). \quad (7.39)$$

The series in the  $O$  term is a geometric series:

$$\sum_{\substack{m \in \mathcal{M} \\ \deg(m) > 0}} \frac{1}{|m|^{2-\epsilon}} = \sum_{n=1}^{\infty} \frac{1}{q^{n(2-\epsilon)}} \#\mathcal{M}_n = \sum_{n=1}^{\infty} \frac{1}{q^{n(1-\epsilon)}} = \frac{1/q^{1-\epsilon}}{1-1/q^{1-\epsilon}} \quad (7.40)$$

and hence tends to 0 as  $q \rightarrow \infty$ , giving (7.37).

## Appendix A. An explicit Chebotarev theorem

We prove an explicit Chebotarev theorem for function fields over finite fields. This theorem is known to experts, cf. [21, Theorem 4.1], [22, Proposition 6.4.8] or [23, Theorem 9.7.10]. However, there it is not given explicitly with the uniformity that we need to use. Therefore, we provide a complete proof.

### (a) Frobenius elements

Let  $\mathbb{F}_q$  be a finite field with  $q$  elements and algebraic closure  $\mathbb{F}$ . We denote by  $\text{Fr}_q$  the Frobenius automorphism  $x \mapsto x^q$ .

Let  $R$  be an integrally closed finitely generated  $\mathbb{F}_q$ -algebra with fraction field  $K$ , and let  $\mathcal{F} \in R[T]$  be a monic separable polynomial of degree  $\deg \mathcal{F} = m$  such that

$$\text{disc } \mathcal{F} \in R^* \tag{A 1}$$

is invertible. Let  $\mathbf{Y} = (Y_1, \dots, Y_m)$  be the roots of  $\mathcal{F}$ , and put

$$S = R[\mathbf{Y}], \quad L = K(\mathbf{Y}) \quad \text{and} \quad G = \text{Gal}\left(\frac{L}{K}\right).$$

We identify  $G$  with a subgroup of  $S_m$  via the action on  $Y_1, \dots, Y_m$ :

$$g(Y_i) = Y_{g(i)}, \quad g \in G \leq S_m. \tag{A 2}$$

By (A 1) and Cramer's rule,  $S$  is the integral closure of  $R$  in  $L$  and  $S/R$  is unramified. In particular, the relative algebraic closure  $\mathbb{F}_{q^\nu}$  of  $\mathbb{F}_q$  in  $L$  is contained in  $S$ . For each  $\nu \geq 0$  we let

$$G_\nu = \{g \in G : g(x) = x^{q^\nu}, \forall x \in \mathbb{F}_{q^\nu}\}, \tag{A 3}$$

the preimage of  $\text{Fr}_q^\nu$  in  $G$  under the restriction map. Since  $\text{Gal}(\mathbb{F}_{q^\nu}/\mathbb{F}_q)$  is commutative,  $G_\nu$  is stable under conjugation.

For every  $\Phi \in \text{Hom}_{\mathbb{F}_q}(S, \mathbb{F})$  with  $\Phi(R) = \mathbb{F}_{q^\nu}$  there exists a unique element in  $G$ , which we call the *Frobenius element* and denote by

$$\left[ \frac{S/R}{\Phi} \right] \in G, \tag{A 4}$$

such that

$$\Phi\left(\left[\frac{S/R}{\Phi}\right]x\right) = \Phi(x)^{q^\nu}, \quad \forall x \in S. \tag{A 5}$$

Since  $S$  is generated by  $\mathbf{Y}$  over  $R$ , it suffices to consider  $x \in \{Y_1, \dots, Y_k\}$  in (A 5). If we further assume that  $\Phi \in \text{Hom}_{\mathbb{F}_{q^\nu}}(S, \mathbb{F})$ , then (A 5) gives that  $[S/R/\Phi]x = x^{q^\nu}$  for all  $x \in \mathbb{F}_{q^\nu}$ , hence

$$\Phi(R) = \mathbb{F}_{q^\nu} \implies \left[ \frac{S/R}{\Phi} \right] \in G_\nu. \tag{A 6}$$

**Lemma A.1.** *For every  $g \in S_m$  and  $\nu \geq 1$  there exists  $V_{g,\nu} = (v_{ij}) \in \text{GL}_m(\mathbb{F})$  such that  $\text{Fr}_{q^\nu}$  acts on the rows of  $V_{g,\nu}$  as  $g$  acts on  $\mathbf{Y}$ :*

$$v_{ij}^{q^\nu} = v_{g(i)j}. \tag{A 7}$$

*Proof.* By replacing  $q$  by  $q^\nu$ , we may assume without loss of generality that  $\nu = 1$ . By relabelling, we may assume without loss of generality that

$$g = (s_1 \cdots e_1)(s_2 \cdots e_2) \cdots (s_k \cdots e_k), \tag{A 8}$$

where  $s_1 = 1$ ,  $s_{i+1} = e_i + 1$  and  $e_k = m$ .

Let  $V$  be the block diagonal matrix

$$V = \begin{pmatrix} V_1 & & & \\ & V_2 & & \\ & & \ddots & \\ & & & V_k \end{pmatrix},$$

where

$$V_i = \begin{pmatrix} 1 & \zeta_i & \cdots & \zeta_i^{\lambda_i-1} \\ 1 & \zeta_i^q & \cdots & \zeta_i^{q(\lambda_i-1)} \\ \vdots & \vdots & & \vdots \\ 1 & \zeta_i^{q^{\lambda_i-1}} & \cdots & \zeta_i^{q^{\lambda_i-1}(\lambda_i-1)} \end{pmatrix}$$

is the Vandermonde matrix corresponding to an element  $\zeta_i \in \mathbb{F}$  of degree  $\lambda_i = e_i - s_i$  over  $\mathbb{F}_q$ . So  $\det V_i = \prod_{1 \leq j' < j \leq \lambda_i} (\zeta_i^{q^{j'-1}} - \zeta_i^{q^{j-1}}) \neq 0$ , hence  $V$  is invertible, and by definition  $\text{Fr}_q$  acts on the rows of  $V$  as the permutation  $g$ . ■

**Lemma A.2.** Let  $\Phi : S \rightarrow \mathbb{F}$  with  $\Phi(R) = \mathbb{F}_{q^v}$  and let  $g \in G_v$ . Then

$$\left[ \frac{S/R}{\Phi} \right] = g \iff V^{-1} \begin{pmatrix} \Phi(Y_1) \\ \vdots \\ \Phi(Y_m) \end{pmatrix} \in \mathbb{F}_{q^v}^m, \quad (\text{A } 9)$$

where  $V = V_{g,v}$  is the matrix from lemma A.1.

*Proof.* Let  $z_1, \dots, z_m \in \mathbb{F}$  be the unique solution of the linear system

$$\Phi(Y_i) = \sum_{j=1}^m v_{ij} z_j, \quad i = 1, \dots, m, \quad (\text{A } 10)$$

i.e.

$$\begin{pmatrix} z_1 \\ \vdots \\ z_m \end{pmatrix} = V^{-1} \begin{pmatrix} \Phi(Y_1) \\ \vdots \\ \Phi(Y_m) \end{pmatrix}.$$

If  $z_i \in \mathbb{F}_{q^v}$ , i.e.  $z_i^{q^v} = z_i$ , we get by applying  $\text{Fr}_{q^v}$  on (A 10) that

$$\Phi(Y_i)^{q^v} = \sum_{j=1}^m v_{ij}^{q^v} z_i = \sum_{j=1}^m v_{g(i)j} z_i = \Phi(Y_{g(i)}).$$

Hence  $[(S/R)/\Phi] = g$  by (A 5).

Conversely, if  $[(S/R)/\Phi] = g$ , then  $\Phi(Y_i)^{q^v} = \Phi(Y_{g(i)})$  by (A 2) and (A 5). We thus get that  $\text{Fr}_{q^v}$  permutes the equations in (A 10), hence  $\text{Fr}_{q^v}$  fixes the unique solution of (A 10). That is to say,  $z_i^{q^v} = z_i$ , as needed. ■

Next, we describe the dependence of the Frobenius element when varying the homomorphisms. For  $\phi \in \text{Hom}_{\mathbb{F}_q}(R, \mathbb{F})$  we define

$$\left( \frac{S/R}{\phi} \right) = \left\{ \left[ \frac{S/R}{\Phi} \right] : \Phi \in \text{Hom}_{\mathbb{F}_{q^\mu}}(S, \mathbb{F}) \text{ prolongs } \phi \right\}. \quad (\text{A } 11)$$

Unlike the case when working with ideals, this set is not a conjugacy class in  $G$ , as we fix the action on  $\mathbb{F}_{q^\mu}$ . However, as we will prove below, the group  $G_0$  acts regularly on  $((S/R)/\phi)$  by conjugation. In particular, if  $G_0 = G$ , or equivalently if  $L \cap \mathbb{F} = \mathbb{F}_q$  (with  $\mathbb{F}$  denoting an algebraic closure of  $\mathbb{F}_q$ ), then  $((S/R)/\phi)$  is a conjugacy class.

To state the result formally, we recall that a group  $\Gamma$  acts *regularly* on a set  $\Omega$  if the action is free and transitive, i.e. for every  $\omega_1, \omega_2 \in \Omega$  there exists a unique  $\gamma \in \Gamma$  with  $\gamma\omega_1 = \omega_2$ .

**Lemma A.3.** *Let  $\phi \in \text{Hom}_{\mathbb{F}_q}(R, \mathbb{F})$  and let  $H$  be the subset of  $\text{Hom}_{\mathbb{F}_{q^\mu}}(S, \mathbb{F})$  consisting of all homomorphisms prolonging  $\phi$ . Assume that  $\phi(R) = \mathbb{F}_{q^\nu}$ .*

- (1) *The group  $G_0$  defined in (A 3) acts regularly on  $H$  by  $g : \Phi \mapsto \Phi \circ g$ .*
- (2) *For every  $g \in G_0$  and  $\Phi \in H$ , we have*

$$\left[ \frac{S/R}{\Phi \circ g} \right] = g^{-1} \left[ \frac{S/R}{\Phi} \right] g.$$

- (3) *Let  $\Phi \in H$ , let  $g = [S/R/\Phi]$ , let  $H_g = \{\Psi \in H : [S/R/\Psi] = g\}$  and let  $C_{G_0}(g)$  be the centralizer of  $g$  in  $G_0$ . Then  $C_{G_0}(g)$  acts regularly on  $H_g$ .*
- (4)  *$\#H_g = \#G_0/\#C = \#G/\mu \cdot \#C$ , where  $C$  is the conjugacy class of  $g$  in  $G_0$ .*

*Proof.* We consider  $G_0 \leq G$  as subgroups of  $S_m$  via the action on  $Y_1, \dots, Y_m$ . Let  $g \in G_0$  and  $\Phi \in H$ . Then  $g(x) = x$  and  $\Phi(x) = x$ , thus  $\Phi \circ g(x) = x$ , for all  $x \in \mathbb{F}_{q^\mu}$ . Thus,  $\Phi \circ g \in H$ . If  $\Phi \circ g = \Phi$ , then  $\Phi(Y_{g(i)}) = \Phi(Y_i)$  for all  $i$ . Since  $\text{disc } \mathcal{F} \in R^*$  it follows that  $\Phi(\text{disc } \mathcal{F}) \neq 0$ , thus  $\Phi$  maps  $\{Y_1, \dots, Y_m\}$  injectively onto  $\{\Phi(Y_1), \dots, \Phi(Y_m)\}$ . We thus get that  $Y_{g(i)} = Y_i$ , hence  $g$  is trivial. This proves that the action is free.

Next, we prove that the action is transitive. Let  $\Phi, \Psi \in H$ . Then  $\ker \Phi$  and  $\ker \Psi$  are prime ideals of  $S$  that lie over the prime ideal  $\ker \phi$  of  $R$ , hence over the prime  $\ker \phi \mathbb{F}_{q^\mu}$  of  $R\mathbb{F}_{q^\mu}$ . By [24, VII, 2.1], there exists  $g_1 \in \text{Gal}(L/K\mathbb{F}_{q^\mu}) = G_0$  such that  $\ker(\Phi \circ g_1^{-1}) = g_1 \ker \Phi = \ker \Psi$ . Replace  $\Phi$  by  $\Phi \circ g_1^{-1}$  to assume without loss of generality that  $\ker \Phi = \ker \Psi$ . Hence  $\Phi = \alpha \circ \Psi$ , where  $\alpha$  is an automorphism of the image  $\Phi(S) = \Psi(S)$  that fixes both  $\mathbb{F}_{q^\mu}$  and  $\phi(R) = \mathbb{F}_{q^\nu}$ . That is to say,  $\alpha = \text{Fr}_q^\rho$ , where  $\rho$  is a common multiple of  $\nu$  and  $\mu$ . By (A 5)

$$\Phi(x) = \Psi(x)^{q^\rho} = \Psi \left( \left[ \frac{S/R}{\Psi} \right] x \right)^{q^{\rho-\nu}} = \dots = \Psi \left( \left[ \frac{S/R}{\Psi} \right]^{\rho/\nu} x \right),$$

so  $\Phi = \Psi \circ g$ , where  $g = [(S/R)/\Psi]^{\rho/\nu}$ . Since, for  $x \in \mathbb{F}_{q^\mu}$  we have  $g(x) = x^{q^\rho}$  and  $\mu \mid \rho$ , we have  $g(x) = x$ , so  $g \in G_0$ . This finishes the proof of (1).

To see (2) note that

$$\begin{aligned} \Phi \left( g \left[ \frac{S/R}{\Phi \circ g} \right] x \right) &= \Phi \circ g \left( \left[ \frac{S/R}{\Phi \circ g} \right] x \right) \\ &= \Phi \circ g(x)^{q^\nu} = \Phi(gx)^{q^\nu} \\ &= \Phi \left( \left[ \frac{S/R}{\Phi} \right] gx \right), \quad \text{for all } x \in S, \end{aligned}$$

so  $g[(S/R)/\Phi \circ g] = [(S/R)/\Phi]g$  (since  $\Phi$  is unramified), as claimed.

The rest of the proof is immediate, as (3) follows immediately from (1) and (2), and (4) follows from (3).  $\blacksquare$

By (A 6) and lemma A.3, it follows that if  $\Phi(R) = \mathbb{F}_{q^\nu}$ , then  $((S/R)/\phi) \subseteq G_\nu$  is an orbit of the action of conjugation from  $G_0$ .

Let  $C \subseteq G$  be such an orbit, i.e.  $C = C_g = \{hgh^{-1} : h \in G_0\}$ ,  $g \in G_v$ . Then  $C \subseteq G_v$ , since the latter is stable under conjugation (see after (A 3)). The explicit Chebotarev theorem gives the asymptotic probability that  $((S/R)/\phi) = C$ :

$$P_{v,C} = \frac{\#\{\phi \in \text{Hom}_{\mathbb{F}_q}(R, \mathbb{F}) : \phi(R) = \mathbb{F}_{q^v} \text{ and } ((S/R)/\phi) = C\}}{\#\{\phi \in \text{Hom}_{\mathbb{F}_q}(R, \mathbb{F}) : \phi(R) = \mathbb{F}_{q^v}\}}.$$

**Theorem A.4.** *Let  $v \geq 1$ , let  $C \subseteq G_v$  be an orbit of the action of conjugation from  $G_0$ . Then*

$$P_{v,C} = \frac{\#C}{\#G_v} + O_{\deg \mathcal{F}, \text{cmp}(R)}(q^{-1/2}),$$

as  $q \rightarrow \infty$ .

We define  $\text{cmp}(R)$  below.

Before proving this theorem, we need to recall the Lang–Weil estimates, which play a crucial role in the proof of the theorem and in particular give the asymptotic value of the denominator of  $P_{v,C}$ .

Let  $U$  be a closed subvariety of  $\mathbb{A}_{\mathbb{F}_q}^n$  that is geometrically irreducible. Lang–Weil estimates give that

$$\#U(\mathbb{F}_q) = q^{\dim U} + O_{n, \deg U}(q^{\dim U - 1/2}). \quad (\text{A } 12)$$

Note that both  $n$  and  $\deg U$  are stable under base change. This may be reformulated in terms of  $\mathbb{F}_q$ -algebras, to say that if

$$R \cong \mathbb{F}_q[X_1, \dots, X_n, f_0^{-1}]/(f_1, \dots, f_k) \quad (\text{A } 13)$$

then

$$\#\{\phi \in \text{Hom}_{\mathbb{F}_q}(R, \mathbb{F}) : \phi(R) = \mathbb{F}_q\} = q^{v \dim R} + O_{\text{cmp}(R)}(q^{\dim R - 1/2}), \quad (\text{A } 14)$$

provided  $R \otimes \mathbb{F}$  is a domain, where  $\text{cmp}(R)$  is a function of  $\sum \deg f_i$  and  $n$ , taking minimum over all presentations (A 13). By the remark following (A 12), it follows that if two  $\mathbb{F}_q$ -algebras  $S$  and  $S'$  become isomorphic over  $\mathbb{F}$ , then  $\text{cmp}(S')$  is bounded in terms of  $\text{cmp}(S)$ . A final property needed is that if  $R \rightarrow S$  is a finite map of degree  $d$ , then  $\text{cmp}(S)$  is bounded in terms of  $\text{cmp}(R)$  and  $d$ .

*Proof.* Let  $g \in C$ , let  $V = V_{g,v}$  be as in (A 7) and let  $S' = R[\mathbf{Z}]$ , where  $\mathbf{Z} = V^{-1}\mathbf{Y}$ . Note that  $\mathbf{Z}$  is the unique solution of the linear system

$$Y_i = \sum_{j=1}^n v_{ij}Z_j, \quad i = 1, \dots, n. \quad (\text{A } 15)$$

Let  $N = \#\text{Hom}_{\mathbb{F}_q}(S', \mathbb{F}_{q^v})$ . By (A 9), the number of  $\Phi \in \text{Hom}_{\mathbb{F}_q}(S, \mathbb{F})$  with  $[(S/R)/\Phi] = g$  equals  $N$ . By lemma A.3, for each  $\phi$  there exist exactly  $\#G_0/\#C$  homomorphisms  $\Phi \in \text{Hom}_{\mathbb{F}_q}(S, \mathbb{F})$  with  $[(S/R)/\Phi] = g$  prolonging  $\phi$ . Hence,

$$\#\left\{\phi \in \text{Hom}_{\mathbb{F}_q}(R, \mathbb{F}) : \phi(R) = \mathbb{F}_{q^v} \text{ and } \left(\frac{S/R}{\phi}\right) = C\right\} = \#C/\#G_0 \cdot N.$$

Since  $G_v$  is a coset of  $G_0$ ,  $\#G_0 = \#G_v$ . Hence, it suffices to prove that  $N = q^{v \dim R} + O_{\text{cmp}(R), \deg \mathcal{F}}(q^{v \dim R - 1/2})$ . As  $R \rightarrow S'$  is a finite map of degree  $\deg \mathcal{F}$ , we get that  $\dim R = \dim S'$  and  $\text{cmp}(S')$  is bounded in terms of  $\text{cmp}(R)$  and  $\deg \mathcal{F}$ . It suffices to show that  $S' \cap \mathbb{F} \subseteq \mathbb{F}_{q^v}$  since then by (A 14) we have

$$N = q^{v \dim S'} + O_{\text{cmp}(S')} (q^{v \dim S' - 1/2}) = q^{v \dim R} + O_{\text{cmp}(R), \deg \mathcal{F}}(q^{v \dim R - 1/2}),$$

and the proof is done.

Let  $L$  be the fraction field of  $S$  and  $K$  of  $R$ . Since  $L/K$  is Galois and  $L \cap \mathbb{F} = \mathbb{F}_{q^v}$  and since the actions of  $\text{Fr}_{q^v}$  and  $g$  agree on  $\mathbb{F}_{q^v}$ , it follows that there exists an automorphism  $\tau$  of  $L\mathbb{F}$  such that  $\tau|_L = g$  and  $\tau|_{\mathbb{F}} = \text{Fr}_{q^v}$ . By (A 7)  $\tau$  permutes the equations (A 15), hence fixes  $\mathbf{Z}$  and thus  $S'$ . In particular, if  $x \in S' \cap \mathbb{F}$ , then  $x^{q^v} = \tau(x) = x$ , so  $x \in \mathbb{F}_{q^v}$ , as was needed to complete the proof. ■

# Correction to 'Shifted convolution and the Titchmarsh divisor problem over $\mathbb{F}_q[t]$ '

J. C. Andrade, L. Bary-Soroker and Z. Rudnick

*Phil. Trans. R. Soc. A* **373**, 20140308 (28 April 2015; Published online 23 March 2015) (doi:10.1098/rsta.2014.0308)

Two of the equations in the above article contained a typographical error.

Equation (1.17) should read as follows:

$$\frac{1}{q^n} \sum_{f \in \mathcal{M}_n} d_k(f)d_k(f+h) = \binom{n+k-1}{k-1}^2 + O(q^{-1/2}). \quad (1.17)$$

Equation (7.36) should read as follows:

$$\binom{n+k-1}{k-1}^2 = \frac{1}{[(k-1)!]^2} n^{2(k-1)} + \dots \quad (7.36)$$
