Enumeration of tropical curves in abelian surfaces

Thomas Blomme

Online seminar, January 27th 2020
Goal: solve enumerative problems and compute Gromov-Witten invariants.

Tools: tropical geometry and correspondence theorem

Upshot: Refined invariants.
The case of toric surfaces

Definition

Let $\Gamma$ be a metric graph of genus $g$. A tropical curve in $\mathbb{R}^2$ is a map $h : \Gamma \to \mathbb{R}^2$ that is affine with integer slope on the edges and satisfies the balancing condition.
Problem

How many degree $d$ genus $g$ curves passing through $3d + g - 1$ points inside $\mathbb{C}P^2$
Problem

How many degree $d$ genus $g$ curves passing through $3d + g - 1$ points inside $\mathbb{C}P^2$

Let $\mathcal{P}_t = \{(t^{x_i}, t^{y_i})\}$ be a collection of points tropicalizing to $\mathcal{P}$.

Theorem (Mikhalkin, Nishinou-Siebert, Shustin, Tyomkin)

Let $h : \Gamma \rightarrow \mathbb{R}^2$ passing through $\mathcal{P}$. The number of complex curves passing through $\mathcal{P}_t$ and tropicalizing to $\Gamma$ is equal to $m_{\Gamma}^C = \prod m_V$. In particular, the number of curves $N_{d,g}^{\mathbb{T}}(\mathcal{P})$ passing through $\mathcal{P}$ does not depend on $\mathcal{P}$ and is equal to $N_{d,g}^C$. 
Problem

How many degree $d$ genus $g$ curves passing through $3d + g - 1$ points inside $\mathbb{C}P^2$

Let $\mathcal{P}_t = \{(t^{x_i}, t^{y_i})\}$ be a collection of points tropicalizing to $\mathcal{P}$.

Theorem (Mikhalkin, Nishinou-Siebert, Shustin, Tyomkin)

Let $h : \Gamma \rightarrow \mathbb{R}^2$ passing through $\mathcal{P}$. The number of complex curves passing through $\mathcal{P}_t$ and tropicalizing to $\Gamma$ is equal to $m^C_\Gamma = \prod m_V$. In particular, the number of curves $N^T_{d,g}(\mathcal{P})$ passing through $\mathcal{P}$ does not depend on $\mathcal{P}$ and is equal to $N^C_{d,g}$.

Theorem (Itenberg-Mikhalkin)

Replacing $m^C_\Gamma$ by $m^q_\Gamma = \prod \frac{q^{m_V/2} - q^{-m_V/2}}{q^{1/2} - q^{-1/2}}$ yields an invariant count, called refined.
Presentation of the manifolds

How about varieties that are not $\mathbb{R}^2$ but not far from it?
Presentation of the manifolds

- You might change slope when crossing the boundary.
- It corresponds to *line bundle of degree $\delta$ over an elliptic curve*. 

Degree of a curve

**Definition**

A curve is of bidegree \((d_1, d_2)\) if it has \(d_2\) upper unbounded ends and intersects a fiber \(d_1\) times. (counted with weights and multiplicities.)

\[(2, 2)\text{ in } E \times \mathbb{T}P^1\]
\[(2, 2)\text{ in } \mathbb{T}F_1\]
\[(1, 0)\text{ in } \mathbb{T}F_2\]

By balancing condition, \(d_1\) does not depend on the choice of the fiber.
Moduli

A genus $g$ trivalent curve $h : \Gamma \rightarrow \mathbb{T}F_\delta$ has

- $d_2$ upper ends
- $\delta d_1 + d_2$ lower ends
- $3g - 3 + \delta d_1 + 2d_2$ bounded edges

Dimension of its deformation space should be

$$(3g - 3 + \delta d_1 + 2d_2) - 2g + 2.$$
Moduli

A genus $g$ trivalent curve $h : \Gamma \to \mathbb{T}F_\delta$ has

- $d_2$ upper ends
- $\delta d_1 + d_2$ lower ends
- $3g - 3 + \delta d_1 + 2d_2$ bounded edges

Dimension of its deformation space should be

$$(3g - 3 + \delta d_1 + 2d_2) - 2g + 2.$$ 

Proposition

*The moduli space of genus $g$ bidegree $(d_1, d_2)$ curves is of dimension $\delta d_1 + 2d_2 + g - 1$.***

Problem

How many genus $g$ bidegree $(d_1, d_2)$ curves pass through $\delta d_1 + 2d_2 + g - 1$ points in general position?
Correspondence theorem

Definition

The multiplicity of a simple tropical curve is

\[ m^C_\Gamma = \prod m_V. \]

Let \( CF_t \) a family of line bundles over \( CE_t \) that tropicalizes to \( TF \) over \( TE \). Let \( P \) be a complex/tropical configuration of points and \( N_{g,(d_1,d_2)}^{C/T}(P) \) the number of complex/tropical curves passing through \( P \).
Correspondence theorem

Definition

The multiplicity of a simple tropical curve is

\[ m^\mathbb{C}_\Gamma = \prod m_\mathcal{V}. \]

Let \( \mathbb{C}F_t \) a family of line bundles over \( \mathbb{C}E_t \) that tropicalizes to \( \mathbb{T}F \) over \( \mathbb{T}E \). Let \( \mathcal{P} \) be a complex/tropical configuration of points and \( N^\mathbb{C}/\mathbb{T}_{g,(d_1,d_2)}(\mathcal{P}) \) the number of complex/tropical curves passing through \( \mathcal{P} \).

Theorem (B.)

Given a family of points \( \mathcal{P}_t \subset \mathbb{C}F_t \) that tropicalizes to \( \mathcal{P} \subset \mathbb{T}F \), and \( h : \Gamma \to \mathbb{T}F_\delta \) there are \( m^\mathbb{C}_\Gamma \) complex curves passing through \( \mathcal{P}_t \) that tropicalize to \( \Gamma \). In particular,

\[ N^\mathbb{C}_{g,(d_1,d_2)} = N^\mathbb{T}_{g,(d_1,d_2)}, \]

and \( N^\mathbb{T}_{g,(d_1,d_2)}(\mathcal{P}) \) does not depend on \( \mathcal{P} \).
Refined invariants

Replace the complex multiplicity by the \textit{refined multiplicity}:

$$m^q_T = \prod_{V} \frac{q^{m_V/2} - q^{-m_V/2}}{q^{1/2} - q^{-1/2}} \in \mathbb{Z}[q^{\pm1/2}].$$

Let $BG_{g,(d_1,d_2)}(P)$ be the refined count of tropical curves passing through $P$. 
Refined invariants

Replace the complex multiplicity by the *refined multiplicity*:

\[
m^q_\Gamma = \prod_{V} \frac{q^{m_V/2} - q^{-m_V/2}}{q^{1/2} - q^{-1/2}} \in \mathbb{Z}[q^{\pm 1/2}].
\]

Let \( BG_{g,(d_1,d_2)}(P) \) be the refined count of tropical curves passing through \( P \).

**Theorem (B.)**

\( BG_{g,(d_1,d_2)}(P) \) does not depend on \( P \) as long as the choice is generic.

Notice that one has to check tropically the invariance: it does not come from a complex invariance.
A few remarks

- It is possible to define relative invariants by prescribing intersection profile with zero and infinite-section (i.e. weights of the ends).
A few remarks

- It is possible to define relative invariants by prescribing intersection profile with zero and infinite-section (i.e. weights of the ends).
- We have a Caporaso-Harris type formula and floor diagrams to compute invariants.
A few remarks

- It is possible to define relative invariants by prescribing intersection profile with zero and infinite-section (i.e. weights of the ends).
- We have a Caporaso-Harris type formula and floor diagrams to compute invariants.
- You can prove regularity results: quasi-modularity of generating series, piecewise polynomiality of relative invariants.
A few remarks

- It is possible to define relative invariants by prescribing intersection profile with zero and infinite-section (i.e. weights of the ends).
- We have a Caporaso-Harris type formula and floor diagrams to compute invariants.
- You can prove regularity results: quasi-modularity of generating series, piecewise polynomiality of relative invariants.
- Interpretation of refined invariants remains open:
  - Generating series of GW invariants with $\lambda$-classes? (Bousseau)
  - Refined counts for real curves?
  - ?
1. Curves in line bundle over an elliptic curve

2. Curves in abelian surfaces

3. Curves in linear system in abelian surfaces
Degree of a curve

**Definition**

Let $TA = \mathbb{R}^2/\Lambda$. The degree of $\Gamma$ is the matrix $C : \Lambda^* \to \mathbb{Z}^2$ obtained by adding the slopes intersecting the right side and the top side respectively.

\[
\begin{pmatrix}
1 & 0 \\
0 & 1 \\
\end{pmatrix}
\quad \begin{pmatrix}
2 & 0 \\
0 & 3 \\
\end{pmatrix}
\quad \begin{pmatrix}
2 & 1 \\
0 & 1 \\
\end{pmatrix}
\]

**Proposition**

Let $S : \Lambda \to \mathbb{R}^2$ be the inclusion. The matrix $C$ is the degree of a tropical curve if and only if $CS_T$ is symmetric. This is due to the gluing condition.
Degree of a curve

Definition

Let $\mathbb{T}A = \mathbb{R}^2/\Lambda$. The degree of $\Gamma$ is the matrix $C : \Lambda^* \to \mathbb{Z}^2$ obtained by adding the slopes intersecting the right side and the top side respectively.

\[
\begin{pmatrix}
1 & 0 \\
0 & 1 \\
\end{pmatrix}
\]

Proposition

Let $S : \Lambda \to \mathbb{R}^2$ be the inclusion. The matrix $C$ is the degree of a tropical curve if and only if $CS^T$ is symmetric.

This is due to the gluing condition.
**Degree of a curve**

**Proposition**

Let $S : \Lambda \to \mathbb{Z}^2$ be the inclusion. The matrix $C$ is the degree of a tropical curve if and only if $CS^T$ is symmetric.

This is due to the *gluing condition*. 
Dimension of moduli space

The expected dimension is

\[(3g - 3) - 2g + 2 = g - 1.\]

Due to gluing conditions/Menelaus relation:
Dimension of moduli space

The expected dimension is

$$(3g - 3) - 2g + 2 = g - 1.$$  

Due to gluing conditions/Menelaus relation:

**Proposition**

The dimension of the deformation space of genus $g$ curves in class $C$ is $g$.

Curves are *superabundant* but it matches the complex dimensions.

**Problem**

How many genus $g$ curves in the class $C$ pass through $g$ points in general position?
Theorem (Nishinou)

Given a (Mumford) family of abelian surfaces $\mathcal{C}A_t$ with a point configuration $\mathcal{P}_t$ tropicalizing to $\mathcal{P} \subset \mathbb{T}A$, and $h : \Gamma \to \mathbb{T}A$ passing through $\mathcal{P}$, there are $m^C_{\Gamma} = \cdots$ curves passing through $\mathcal{P}_t$ and tropicalizing to $\Gamma$. In particular, $N^C_{g,\mathcal{C}} = N^T_{g,\mathcal{C}}$, that does not depend on $\mathcal{P}$ nor $\mathbb{T}A$. 

The multiplicity is given by $|\ker \Theta \otimes \mathcal{C}^*|$ where $\Theta$ is a map between some lattices. In the toric case, the lattices have the same dimension. We compute with the determinant and get $\prod m^V_{\Gamma}$. Here, domain is rank one less than codomain.

Theorem (B.)

The multiplicity expresses as $m^C_{\Gamma} = \delta^\Gamma \prod m^V_{\Gamma}$, where $\delta^\Gamma = \gcd w_e$. 

Thomas Blomme

Enumeration of tropical curves in abelian surfaces

Online seminar, January 27th 2020
Correspondence theorem

**Theorem (Nishinou)**

Given a (Mumford) family of abelian surfaces $\mathcal{C}A_t$ with a point configuration $\mathcal{P}_t$ tropicalizing to $\mathcal{P} \subset TA$, and $h : \Gamma \rightarrow TA$ passing through $\mathcal{P}$, there are $m^C_{\Gamma} = \cdots$ curves passing through $\mathcal{P}_t$ and tropicalizing to $\Gamma$. In particular, $N^C_{g,C} = N^T_{g,C}$, that does not depend on $\mathcal{P}$ nor $TA$.

- The multiplicity is given by $| \ker \Theta \otimes \mathbb{C}^* | \prod w_e$ where $\Theta$ is a map between some lattices.
- In the toric case, the lattices have the same dimension. We compute with the determinant and get $\prod m_V$.
- Here, domain is rank one less than codomain.
Correspondence theorem

**Theorem (Nishinou)**

Thomas Blomme

Enumeration of tropical curves in abelian surfaces

Online seminar, January 27th 2020
The multiplicity is 1 on the left and $2 \cdot 4 \cdot 4 = 32$ on the right.
Refined invariants

Replace the complex multiplicity by the \textit{refined multiplicity}:

\[(\delta_{\Gamma})m_{\Gamma}^q = (\delta_{\Gamma}) \prod_{V} \frac{q^{m_{V}/2} - q^{-m_{V}/2}}{q^{1/2} - q^{-1/2}} \in \mathbb{Z}[q^{\pm 1/2}].\]

Let \(BG_{g,C(,k)}(\mathbb{T}A, \mathcal{P})\) be the refined count of genus \(g\), degree \(C\) \((,\gcd k)\) tropical curves passing through \(\mathcal{P}\) with multiplicity \((\delta_{\Gamma})m_{\Gamma}^q\).
Refined invariants

Replace the complex multiplicity by the \textit{refined multiplicity}:

\[
(\delta \Gamma)m^q_{\Gamma} = (\delta \Gamma) \prod V q^{m_V/2} - q^{-m_V/2} \frac{q^{1/2} - q^{-1/2}}{q^{1/2} - q^{-1/2}} \in \mathbb{Z}[q^{\pm 1/2}].
\]

Let $BG_{g,C,(,k)}(TA, P)$ be the refined count of genus $g$, degree $C$ ($,\gcd k$) tropical curves passing through $P$ with multiplicity $(\delta \Gamma)m^q_{\Gamma}$.

**Theorem (B.)**

$BG_{g,C,(,k)}(TA, P)$ does not depend on $P$ nor $TA$ as long as the choice is generic.

Notice that one has to check tropically the invariance: it does not come from a complex invariance.
A few remarks

- We have circular floor diagrams to make computations.
- You can prove regularity statements such as the quasi-modularity of certain generating series.
- Interpretation of refined invariants remains open.
1 Curves in line bundle over an elliptic curve

2 Curves in abelian surfaces

3 Curves in linear system in abelian surfaces
Previously, curves of genus $g$ through $g$ points. Complement of marked points is without cycle.
Now, fix $g - 2$ points and the linear system. (⇒ no translations anymore)

In other words, you fix a curve $\Gamma_0$ of degree $C$, and ask for $\Gamma - \Gamma_0$ to be the corner locus of an piecewise affine function.
You can assume that $\Gamma_0$ is of genus 2 and the boundary of a fundamental domain.
Correspondence theorem

Theorem (B.)

Given a (Mumford) family of abelian surfaces $\mathcal{CA}_t$ with a point configuration $\mathcal{P}_t$ tropicalizing to $\mathcal{P} \subset \mathbb{T}A$ and a linear system, and $h : \Gamma \to \mathbb{T}A$ tropical solution, there are $m^C_\Gamma = \cdots$ curves in the linear system passing through $\mathcal{P}_t$ and tropicalizing to $\Gamma$. In particular, $N_{g,C}^{FLS,T} = N_{g,C}^{FLS,C}$, that does not depend on $\mathcal{P}$ nor $\mathbb{T}A$.

The multiplicity is given by $| \ker \Psi \otimes \mathbb{C}^* | \prod w_e$ where $\Psi$ is a map between some lattices.
Correspondence theorem

**Theorem (B.)**

*Given a (Mumford) family of abelian surfaces $\mathbb{C}A_t$ with a point configuration $P_t$ tropicalizing to $P \subset \mathbb{T}A$ and a linear system, and $h : \Gamma \rightarrow \mathbb{T}A$ tropical solution, there are $m_{\Gamma}^C = \cdots$ curves in the linear system passing through $P_t$ and tropicalizing to $\Gamma$. In particular, $N^{FLS,C}_{g,C} = N^{FLS,T}_{g,C}$, that does not depend on $P$ nor $\mathbb{T}A$.*

The multiplicity is given by $|\ker \Psi \otimes \mathbb{C}^*| \prod w_e$ where $\Psi$ is a map between some lattices.

**Theorem (B.)**

*The multiplicity expresses as $m_{\Gamma}^C = \delta_{\Gamma} \Lambda_{\Sigma} \prod m_\mathcal{V}$, where $\delta_{\Gamma} = \text{gcd} w_e$, and $\Lambda_{\Sigma}$ is the index of $H_1(\Sigma)$ inside $H_1(\mathbb{T}A) \simeq \Lambda$.***
Deformation of the curve when moving a marked point.

\[ m^C_\Gamma = 4 \]
Refined invariants

Replace the complex multiplicity by the \textit{refined multiplicity}: 

\[(\delta_G)^{\Sigma} \Lambda_{\Gamma}^\Sigma m_{\Gamma} = (\delta_G)^{\Sigma} \Lambda_{\Gamma}^\Sigma \prod_{V} \frac{q^{m_{V}/2} - q^{-m_{V}/2}}{q^{1/2} - q^{-1/2}} \in \mathbb{Z}[q^{\pm 1/2}].\]

Let \(BG_{g,C(,k)}^{FLS}(\mathbb{T}A, P)\) be the refined count of genus \(g\), degree \(C\) (\(gcd\) \(k\)) tropical curves passing through \(P\) in a fixed linear system with multiplicity \((\delta_G)^{\Sigma} \Lambda_{\Gamma}^\Sigma m_{\Gamma}\).
Refined invariants

Replace the complex multiplicity by the \textit{refined multiplicity}:

\[(\delta_{\Gamma})^{\Sigma} \Lambda_{\Gamma} m_{\Gamma}^{q} = (\delta_{\Gamma})^{\Sigma} \Lambda_{\Gamma} \prod_{V} \frac{q^{mv/2} - q^{-mv/2}}{q^{1/2} - q^{-1/2}} \in \mathbb{Z}[q^{\pm 1/2}].\]

Let \(BG_{g,C,(,k)}^{FLS}(\mathbb{T}A, \mathcal{P})\) be the refined count of genus \(g\), degree \(C\), \(gcd\ k\) tropical curves passing through \(\mathcal{P}\) in a fixed linear system with multiplicity \((\delta_{\Gamma})^{\Sigma} m_{\Gamma}^{q}\).

**Theorem (B.)**

\(BG_{g,C,(,k)}^{FLS}(\mathbb{T}A, \mathcal{P})\) \textit{does not depend on} \(\mathcal{P}\) \textit{nor} \(\mathbb{T}A\) \textit{as long as the choice is generic}.

Notice that one has to check tropically the invariance: it does not come from a complex invariance.
A few remarks

- We have circular floor diagrams to make computations.
- You can prove regularity statements such as the quasi-modularity of certain generating series.
- Interpretation of refined invariants remains open.
- It would be interesting if the new term $\Lambda^\Sigma$ also had a refinement.
Thanks!
